Abstract

A distributional solution framework is developed for systems consisting of linear hyperbolic partial differential equations and switched differential-algebraic equations (DAEs) which are coupled via boundary conditions. The unique solvability is then characterize in terms of a switched delay DAE. The theory is illustrated with an example of electric power lines modelled by the telegraph equations which are coupled via a switching transformer where simulations confirm the predicted impulsive solutions.

Keywords Solution theory · Coupled systems · Switched systems · Partial differential equations · Differential algebraic equations

1 Introduction

In this paper, we develop a rigorous solution theory for systems where a linear hyperbolic partial differential equation (PDE) is coupled with a switched differential-algebraic equation (DAE) via boundary conditions (BC), see Fig. 1 as an overview.

Such systems occur, for example, when modelling power grids using the telegraph equation [8] including switches (e.g. induced by disconnecting lines), water flow

Fig. 1 Coupling of a PDE with a switched DAE via boundary condition

networks with valves [13,14], supply chain models including processor breakdown [1,7], district heating systems with rapid consumption changes [5] and blood flow with simplified valve models in the heart [15]. Similar to [3,11] the closed-loop setting illustrated in Fig. 1 can include general network structures.

In this coupled system, the output of the switched DAE provides the boundary condition for the PDE and the boundary values of the PDE serve as input to the DAE. Solutions of switched DAEs in general contain jumps and derivatives thereof, e.g. derivatives of Dirac impulses [17,19]; hence, the solution concept of the PDE has to be extended to allow for jumps, Dirac impulses and their derivatives at the boundary. In particular, this is a wider class compared to the solutions of small bounded variation, e.g. used in [4] where a nonlinear hyperbolic PDE is coupled to an ODE. Similarly, in [2,12], the investigations of switched linear PDEs with source terms are restricted to solutions with bounded variation. In [16], Dirac impulses are introduced at the position of an interface of nonlinear PDEs. A more general appearance of Dirac impulses is allowed in [6,23] for a partially linear system. A detailed overview of existing solution concepts for linear hyperbolic PDEs is given in [10].

Since arbitrary high derivatives of Dirac impulses can occur as solutions of switched DAEs, the aforementioned approaches are not suitable to handle the coupled systems studied here. Indeed, our first main contribution is a suitable extension of the 1D piecewise-smooth distributional solution framework (developed to handle switched DAEs in [17,18]) to a 2D piecewise-smooth distributional solution framework. This new class of solutions is large enough to allow distributional solutions such as Dirac impulses and their derivatives. At the same time, its elements are regular enough to allow a trace evaluation on the boundaries of the domain.

Towards our main existence and uniqueness result for solutions of the coupled system, we also establish a relationship between the solutions of the coupled systems and the solution of a switched *delay* DAE. For the latter, we generalize a recent existence and uniqueness result for delay DAEs in [20].

This paper is structured as follows.

After a detailed description of the coupled system (including an example of a simple power network), we review the classical solution theory of linear hyperbolic PDEs in Sect. 3 and the solution theory of switched DAEs in Sect. 4. The novel distributional solution framework for linear hyperbolic PDEs is introduced in Sect. 5 which is then used in Sect. 6 to establish a link between the coupled system and the solutions of a switched delay DAE (Theorem 23). Finally, we establish an existence and uniqueness result for general switched delay DAE (Theorem 24) and can conclude our main result

about the existence and uniqueness of solutions of the coupled system (Corollary 26). We illustrate the results by numerical simulations of the power grid example.

2 Problem setup

2.1 System class

We consider linear hyperbolic PDEs on a bounded interval of the form:

$$\partial_t \mathbf{u}(t, x) + \mathbf{A} \partial_x \mathbf{u}(t, x) = 0, \quad x \in [a, b], \quad t \geq t_0, \quad (2.1a)$$

$$\mathbf{y}_P(t) = \mathbf{C}_P \mathbf{u}_{ab}(t), \quad t \geq t_0 \quad (2.1b)$$

where $a, b, t_0 \in \mathbb{R}$ with $a < b$, $\mathbf{u} : [t_0, \infty) \times [a, b] \rightarrow \mathbb{R}^n$, $n \in \mathbb{N}$, is the n -dimensional vector of unknowns of the PDE, $\mathbf{A} \in \mathbb{R}^{n \times n}$ and $\mathbf{y}_P : [t_0, \infty) \rightarrow \mathbb{R}^v$, $v \in \mathbb{N}$ is the v -dimensional output of the PDE depending on $\mathbf{u}_{ab}(t) := (\mathbf{u}(t, a)^\top, \mathbf{u}(t, b)^\top)^\top \in \mathbb{R}^{2n}$ and $\mathbf{C}_P \in \mathbb{R}^{v \times 2n}$. The boundary conditions (BC) of the PDE have the form:

$$\mathbf{P} \mathbf{u}_{ab}(t) = \mathbf{y}_D(t), \quad t > t_0, \quad (2.1c)$$

where $\mathbf{P} \in \mathbb{R}^{n \times 2n}$ and $\mathbf{y}_D : [t_0, \infty) \rightarrow \mathbb{R}^n$ is the output of the switched DAE

$$\mathbf{E}_\sigma \dot{\mathbf{w}}(t) = \mathbf{H}_\sigma \mathbf{w}(t) + \mathbf{B}_\sigma \mathbf{y}_P(t) + \mathbf{f}_\sigma(t), \quad t \geq t_0, \quad (2.1d)$$

$$\mathbf{y}_D(t) = \mathbf{C}_{D\sigma} \mathbf{w}(t), \quad t \geq t_0, \quad (2.1e)$$

with the m -dimensional vector of unknowns $\mathbf{w} : [t_0, \infty) \rightarrow \mathbb{R}^m$, $m \in \mathbb{N}$, the switching signal $\sigma : \mathbb{R} \rightarrow \{1, 2, \dots, N\}$, $N \in \mathbb{N}$, and $\mathbf{E}_\xi, \mathbf{H}_\xi \in \mathbb{R}^{m \times m}$, $\mathbf{B}_\xi \in \mathbb{R}^{m \times v}$, $\mathbf{f}_\xi : [t_0, \infty) \rightarrow \mathbb{R}^m$, $\mathbf{C}_{D\xi} \in \mathbb{R}^{n \times m}$ for each $\xi \in \{1, 2, \dots, N\}$.

The coupled system (2.1) has to be equipped with initial conditions

$$\mathbf{u}(t_0, x) = \mathbf{u}^{t_0}(x), \quad x \in [a, b], \quad (2.2a)$$

$$\mathbf{w}(t_0) = \mathbf{w}^{t_0}, \quad (2.2b)$$

where $\mathbf{u}^{t_0} : [a, b] \rightarrow \mathbb{R}^n$ and $\mathbf{w}^{t_0} \in \mathbb{R}^m$.

Remark 1 We would like to stress that the coupling structure in (2.1) is quite general; in fact, arbitrary networks whose edges represent PDEs and whose nodes represent (switched) DAEs which couple the different PDEs are covered. Consider, for example, a network as illustrated in Fig. 2a, where on each edge \mathcal{E} the quantity $\mathbf{u}^\mathcal{E}$ is governed by a linear PDE $\mathbf{u}_t^\mathcal{E} + \mathbf{A} \mathbf{u}_x^\mathcal{E} = 0$.

At each node s , algebraic and/or differential conditions combine possible internal states \mathbf{w}^s with certain boundary values \mathbf{q}^s of the connected $\mathbf{u}^\mathcal{E}$, i.e. $\mathbf{E}_\sigma^s \dot{\mathbf{w}}^s = \mathbf{H}_\sigma^s \mathbf{w}^s + \mathbf{B}_\sigma^s \mathbf{q}^s + \mathbf{f}_\sigma^s$. This setup can be rewritten in the form (2.1) by first rescaling the spatial domain (which simply modifies the matrices $\mathbf{A}^\mathcal{E}$ by a constant multiple) so that all PDEs are defined on the same interval and can be viewed as a single PDE where the new

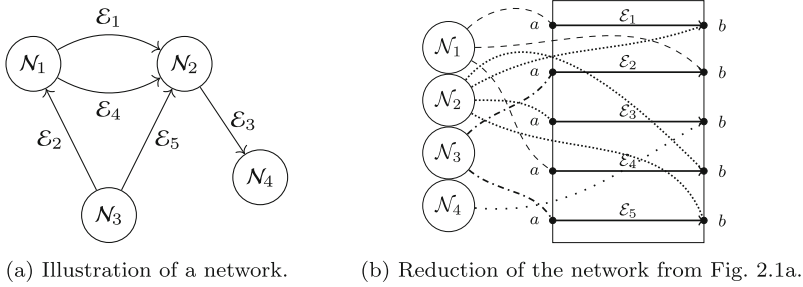

Fig. 2 An example of a network consisting of four nodes and five connecting edges and how to reduce it to one node and one edge (loop) network which still has all the features of the original network

unknown \mathbf{u} consists of the unknowns $\mathbf{u}^\mathcal{E}$ of each edge stacked over each other. (The \mathbf{A} -matrix then is a block diagonal matrix.) In a similar way, the switched differential-algebraic equations for each node can be stacked over each other (resulting in block diagonal coefficient matrices) and can then be viewed as single switched DAE, see Fig. 2b. A similar reduction is used in [3,11]. This method is also used in the specific example of a simple power grid discussed in Sect. 2.3.

2.2 Ill-posed coupling

As mentioned in the introduction, coupling a PDE to a switched DAE is challenging due to the need to consider distributional boundary terms. However, there is another challenge due to the additional algebraic constraints present in a DAE. The following example illustrates that even if the PDE is well-posed (i.e. it has a unique solutions for all initial and boundary conditions) and the DAE is well-posed (i.e. it has unique solutions for all consistent initial values and for all sufficiently smooth input signals), the coupled system is ill-posed.

Example 2 Consider the scalar advection equation given by

$$\partial_t v(t, x) + \partial_x v(t, x) = 0, \quad t \in [0, \infty), \quad x \in [0, 1], \tag{2.3}$$

with initial condition $v(0, x) = v_0(x)$, boundary condition $v(t, 0) = b(t)$, input $b(\cdot)$ and output $y_P(t) := v(t, 0)$. It is well known that there exists a unique solution to (2.3) for any sufficiently smooth $v_0(\cdot)$ and $b(\cdot)$. This PDE will be coupled to the following (nonswitched) DAE given by

$$\begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} \dot{w} \\ z \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} w \\ z \end{bmatrix} - \begin{bmatrix} 0 \\ 1 \end{bmatrix} q, \tag{2.4}$$

with input $q(\cdot)$ and output $y_D(t) := [0 \quad 1] \begin{bmatrix} w \\ z \end{bmatrix}$. It is easily seen that for all $q(\cdot)$ and all initial values for $w(0)$ there exists a unique solution.

Now let (2.3) be coupled with (2.4) via $b(t) = y_D(t)$ and $q(t) = y_P(t)$. Since by construction $b(t) = y_P(t)$, this coupling leads to $q(t) = y_D(t) = z(t)$, which means

that the DAE changes to

$$\begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} \dot{w} \\ \dot{z} \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} w \\ z \end{bmatrix} - \begin{bmatrix} 0 \\ 1 \end{bmatrix} z = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} w \\ z \end{bmatrix}.$$

However, in this new DAE, the variable z is completely free, which also means that the boundary of the PDE is completely free, i.e. the coupled system does not have a unique solution anymore.

For this simple example, it is easy to see why well-posedness of the coupled system is lost: The PDE has as an “output” the same value as the provided boundary value; hence, both values are not independent and cannot be coupled via a DAE in an arbitrary way. In fact, just choosing a different output for the DAE (e.g. $y_D = [1 \ 0] \begin{bmatrix} w \\ z \end{bmatrix}$) results in a well-posed coupled system.

In general, it will not be so apparent as in the above example which couplings lead to a well-posed system and it is therefore necessary to better understand the underlying solution structure.

2.3 Power grid example

Consider the simple electrical power grid illustrated in Fig. 3.

Each line is modelled by the telegraph equation of the form:

$$\begin{aligned} \partial_t I(t, x) + \frac{1}{L} \partial_x V(t, x) &= 0 \\ \partial_t V(t, x) + \frac{1}{C} \partial_x I(t, x) &= 0, \end{aligned} \tag{2.5}$$

where $t \geq 0$, $x \in [0, \ell]$, $I(t, x)$ stands for the current, $V(t, x)$ is the voltage and the constants L and C are inductance and capacitance, respectively. In particular, each line k has a position-dependent current I_k and voltage V_k . By appropriate scaling of the coefficients in the telegraph equation, we can assume that all PDEs are defined on the common domain $T \times X = [0, \infty) \times [a, b]$. At the nodes, there is a coupling between corresponding boundary values, where the “outputs” of the telegraph equations are the boundary currents I_k for each line k . A generator is located at the first node, where

Fig. 3 Simple electrical power grid with one generator node, one switching transformer node and two consumption nodes

we assume an externally given voltage. This algebraic constraint is modelled by the algebraic relations:

$$0 = z_1 - v_G, \tag{2.6a}$$

$$y_D^G = z_1, \tag{2.6b}$$

where $v_G(\cdot)$ is the externally given (time-varying) voltage of the generator together with the boundary condition $V_1(\cdot, a^+) = y_D^G$. On the consumption nodes, all voltages are assumed to be equal and we assume that the consumption is modelled as a simple Ohm's resistance, i.e. the sum of the (directed) currents at the boundary of the lines is proportional to the voltage at the node, and this is modelled by the DAEs

$$\begin{aligned} 0 &= z_{24} - R_{24}(I_4(\cdot, a^+) - I_2(\cdot, b^-)), & y_D^{24} &= z_{24}, \\ 0 &= z_{34} - R_{34}(I_3(\cdot, b^-) + I_4(\cdot, b^-)), & y_D^{34} &= z_{34}, \end{aligned} \tag{2.7}$$

where $R_{24}, R_{34} > 0$ are the resistive loads. Further, we impose the boundary conditions

$$\begin{aligned} V_2(\cdot, b^-) &= y_D^{24}, & V_3(\cdot, b^-) &= y_D^{34}, \\ V_4(\cdot, a^+) &= y_D^{24}, & V_4(\cdot, b^-) &= y_D^{34}. \end{aligned}$$

Finally, the switching transformer node is governed by the electric circuit given in Fig. 4.

The switch-independent equations governing this switching transformer node are as follows:

$$L_{12} \frac{d}{dt} i_{12} = v_{12}, \quad L_{13} \frac{d}{dt} i_{13} = v_{13}, \tag{2.8}$$

Fig. 4 A node connecting three power lines with switching transformers

with output

$$y_D^2 = \kappa_{12}v_{12}, \quad y_D^3 = \kappa_{13}v_{13},$$

where $\kappa_{12}, \kappa_{13} > 0$ are the voltage amplification constants. Note that, in this example, we use amplifiers only for the voltage values, so the power grid example is a simplified model.

If the switch connects line 1 and 2, then the following two algebraic constraints hold

$$0 = i_{12} - I_1(\cdot, b^-), \quad 0 = i_{13}$$

together with the output $y_D^1 = v_{12}$ and, otherwise,

$$0 = i_{12}, \quad 0 = i_{13} - I_1(\cdot, b^-)$$

with output $y_D^1 = v_{13}$. Let $\tilde{\mathbf{w}} = (i_{12}, i_{13}, v_{12}, v_{13})^\top$, then the rules governing the switching transformer node can be compactly written as a switched DAE

$$\begin{aligned} \tilde{\mathbf{E}}_\sigma \dot{\tilde{\mathbf{w}}} &= \tilde{\mathbf{H}}_\sigma \tilde{\mathbf{w}} + \tilde{\mathbf{B}}_\sigma \tilde{\mathbf{q}} \\ \tilde{\mathbf{y}}_D &= \tilde{\mathbf{C}}_{D_\sigma} \tilde{\mathbf{w}}, \end{aligned}$$

where

$$\begin{aligned} \tilde{\mathbf{E}}_1 = \tilde{\mathbf{E}}_2 &= \begin{bmatrix} L_{12} & 0 & 0 & 0 \\ 0 & L_{13} & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}, & \tilde{\mathbf{H}}_1 = \tilde{\mathbf{H}}_2 &= \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix}, \\ \tilde{\mathbf{B}}_1 &= \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} =: [\tilde{\mathbf{B}}_1^1, \mathbf{0}, \mathbf{0}], & \tilde{\mathbf{B}}_2 &= \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \end{bmatrix} =: [\tilde{\mathbf{B}}_2^1, \mathbf{0}, \mathbf{0}], \\ \tilde{\mathbf{C}}_{D_1} &= \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & \kappa_{12} & 0 \\ 0 & 0 & 0 & \kappa_{13} \end{bmatrix}, & \tilde{\mathbf{C}}_{D_2} &= \begin{bmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & \kappa_{12} & 0 \\ 0 & 0 & 0 & \kappa_{13} \end{bmatrix}, \end{aligned}$$

with

$$\tilde{\mathbf{q}} = (I_1(\cdot, b^-), I_2(\cdot, a^+), I_3(\cdot, a^+))^\top, \quad \tilde{\mathbf{y}}_D = (y_D^1, y_D^2, y_D^3)^\top.$$

The coupling via the boundaries of the lines 1, 2 and 3 is as follows:

$$V_1(\cdot, b^-) = y_D^1, \quad V_2(\cdot, a^+) = y_D^2, \quad V_3(\cdot, a^+) = y_D^3.$$

Thus, the overall coupled system has the form (2.1) with

$$\mathbf{A} = \begin{bmatrix} \mathbf{A}_1 & 0 & 0 & 0 \\ 0 & \mathbf{A}_2 & 0 & 0 \\ 0 & 0 & \mathbf{A}_3 & 0 \\ 0 & 0 & 0 & \mathbf{A}_4 \end{bmatrix} \text{ where } \mathbf{A}_j = \begin{bmatrix} 0 & \frac{1}{\tau_j L_j} \\ \frac{1}{\tau_j C_j} & 0 \end{bmatrix} \text{ for each } j = 1, 2, 3, 4, \tag{2.9}$$

$\mathbf{u} = (\mathbf{u}_1^\top, \mathbf{u}_2^\top, \mathbf{u}_3^\top, \mathbf{u}_4^\top)^\top$ with $\mathbf{u}_j = (I_j, V_j)^\top$, and the output of the PDE (used as an input to the switched DAE) is all currents at the boundaries of the lines, i.e.

$$\mathbf{C}_P = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \end{bmatrix},$$

the switched DAE has the state vector $\mathbf{w} = (z_1, i_{12}, i_{13}, v_{12}, v_{13}, z_{24}, z_{34})^\top$, coefficient matrices

$$\begin{aligned} \mathbf{E}_k &= \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & \tilde{\mathbf{E}}_k & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}, \quad \mathbf{H}_k = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \tilde{\mathbf{H}}_k & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}, \\ \mathbf{B}_k &= \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \tilde{\mathbf{B}}_k^1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -R_{24} & 0 & R_{24} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & -R_{34} & -R_{34} \end{bmatrix}, \\ \mathbf{C}_{Dk} &= \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & [0,1,0] & 0 & 0 \\ 0 & [0,0,1] & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & [1,0,0] & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \tilde{\mathbf{C}}_{Dk} & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}, \quad \mathbf{f}_k = \begin{bmatrix} -v_G \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}, \end{aligned} \tag{2.10}$$

where $k = 1, 2$ and the coupling matrix $\mathbf{P} = \begin{bmatrix} \mathbf{P}_a & 0 \\ 0 & \mathbf{P}_b \end{bmatrix}$ is given by

$$\mathbf{P}_a = \mathbf{P}_b = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}.$$

3 Linear hyperbolic PDEs

In this section, we recall the solution properties of a system of linear PDEs on a bounded spatial domain

$$\partial_t \mathbf{u}(t, x) + \mathbf{A} \partial_x \mathbf{u}(t, x) = 0, \quad x \in [a, b], \quad t \geq t_0, \tag{3.1}$$

where t_0 is the initial time for the system, $\mathbf{u} : [t_0, \infty) \times [a, b] \rightarrow \mathbb{R}^n$ is the n -dimensional unknown vector and $\mathbf{A} \in \mathbb{R}^{n \times n}$ with the prescribed initial condition

$$\mathbf{u}(t_0, x) = \mathbf{u}^{t_0}(x), \quad x \in [a, b]. \tag{3.2}$$

Assumption 1 The system (3.1) is assumed to be hyperbolic, i.e. \mathbf{A} is assumed to be nonsingular and diagonalizable by a real coordinate transformation.

Under Assumption 1, there exists a nonsingular matrix $\mathbf{R} \in \mathbb{R}^{n \times n}$ such that

$$\mathbf{R}^{-1} \mathbf{A} \mathbf{R} = \text{diag}(\lambda_1, \lambda_2, \dots, \lambda_n),$$

where $\lambda_i, i = 1, \dots, n$, are the (real) eigenvalues of \mathbf{A} . The matrix \mathbf{R} is composed of the eigenvectors \mathbf{r}_i corresponding to the eigenvalues λ_i of \mathbf{A} . Without restricting generality (and under the nonsingularity assumption of \mathbf{A}), we can assume that $\lambda_1 \leq \lambda_2 \leq \dots \leq \lambda_{n-r} < 0 < \lambda_{n-r+1} \leq \dots \leq \lambda_{n-1} \leq \lambda_n$, where $r \in \{0, 1, \dots, n\}$ is the number of positive eigenvalues of \mathbf{A} . Finally, we let $\Lambda := \text{diag}(\lambda_1, \lambda_2, \dots, \lambda_n)$ and $\mathbf{R} = [\mathbf{R}^-, \mathbf{R}^+]$, where the columns of the matrices \mathbf{R}^- and \mathbf{R}^+ consist of the eigenvectors that correspond to negative and positive eigenvalues of \mathbf{A} , respectively.

By applying the coordinate transformation $\mathbf{v} = \mathbf{R}^{-1}\mathbf{u}$, we see that (3.1) is equivalent to a decoupled system of scalar PDEs, $i = 1, 2, \dots, n$,

$$\partial_t v_i(t, x) + \lambda_i \partial_x v_i(t, x) = 0 \tag{3.3a}$$

$$v_i(t_0, x) =: v_i^{t_0}(x), \tag{3.3b}$$

where $v_i^{t_0} = \mathbf{r}_i \mathbf{u}^{t_0}$, where \mathbf{r}_i is the i -th row vector of \mathbf{R}^{-1} .

On a bounded spatial domain, say $x \in [a, b]$, it is necessary to prescribe some boundary conditions at the boundaries $x = a$ and $x = b$. The system (3.1) needs as many boundary conditions at $x = a$ as the number of positive eigenvalues and as many boundary conditions at $x = b$ as the number of negative eigenvalues. The boundary conditions are defined as:

$$\begin{aligned} \mathbf{P}_a \mathbf{u}(t, a) &= \mathbf{b}^a(t), \\ \mathbf{P}_b \mathbf{u}(t, b) &= \mathbf{b}^b(t), \end{aligned} \quad t > t_0, \tag{3.4}$$

where $\mathbf{P}_a \in \mathbb{R}^{r \times n}$, $\mathbf{P}_b \in \mathbb{R}^{(n-r) \times n}$, $\mathbf{b}^a : \mathbb{R} \rightarrow \mathbb{R}^r$ and $\mathbf{b}^b : \mathbb{R} \rightarrow \mathbb{R}^{n-r}$. For the well-posedness of the boundary condition (2.1c) for the hyperbolic PDE (3.1) satisfying Assumption 1, we will impose the following assumption on the coupling matrix \mathbf{P} .

Assumption 2 The coupling matrix in (2.1c) has the block structure $\mathbf{P} = \begin{bmatrix} \mathbf{P}_a & 0 \\ 0 & \mathbf{P}_b \end{bmatrix}$ where $\mathbf{P}_a \in \mathbb{R}^{r \times n}$ and $\mathbf{P}_b \in \mathbb{R}^{(n-r) \times n}$ satisfy

$$\ker \mathbf{P}_a \oplus \text{im } \mathbf{R}^+ = \mathbb{R}^n \quad \text{and} \quad \ker \mathbf{P}_b \oplus \text{im } \mathbf{R}^- = \mathbb{R}^n.$$

For the boundary conditions (3.4) in the characteristic variables, we define $\mathbf{M} = [\mathbf{M}_1 \ \mathbf{M}_2] \in \mathbb{R}^{r \times n}$ and $\mathbf{N} = [\mathbf{N}_1 \ \mathbf{N}_2] \in \mathbb{R}^{(n-r) \times n}$ by

$$\begin{bmatrix} \mathbf{P}_a \mathbf{R}^- & \mathbf{P}_a \mathbf{R}^+ \\ \mathbf{P}_b \mathbf{R}^- & \mathbf{P}_b \mathbf{R}^+ \end{bmatrix} = \begin{bmatrix} \mathbf{M}_1 & \mathbf{M}_2 \\ \mathbf{N}_1 & \mathbf{N}_2 \end{bmatrix}.$$

From Assumption 2, it is easily seen that \mathbf{M}_2 and \mathbf{N}_1 are invertible, and we therefore can transform (3.4) as follows:

$$\begin{aligned} \mathbf{v}_+^a(t) &:= \mathbf{v}_+(t, a) = -\mathbf{M}_2^{-1} \mathbf{M}_1 \mathbf{v}_-(t, a) + \mathbf{M}_2^{-1} \mathbf{b}^a(t), \\ \mathbf{v}_-^b(t) &:= \mathbf{v}_-(t, b) = -\mathbf{N}_1^{-1} \mathbf{N}_2 \mathbf{v}_+(t, b) + \mathbf{N}_1^{-1} \mathbf{b}^b(t), \end{aligned} \quad t > t_0. \tag{3.5}$$

Remark 3 In the case that the wave speed $\lambda_i = 0$, Eq. (3.3) is simply $\partial_t v_i = 0$, meaning that the change in the solution with respect to time is zero, with the initial condition given as in (3.3b). Hence, the solution is given by the initial condition $v_i(t, x) = v_i^{t_0}(x)$.

3.1 Explicit solution formula in terms of characteristic variables

In order to give a solution formula in a compact form, we define two shift operators as follows.

Definition 4 (Shift operator for functions) Denote with $\mathcal{F}(A \rightarrow B)$ the set of all functions from some set A to some set B . Let $T \subseteq \mathbb{R}$ and $X \subseteq \mathbb{R}$, then the *time shift operator* $\mathcal{S}_{\text{time}}^{\lambda, x_0}$ with speed $\lambda \in \mathbb{R}$ and initial position $x_0 \in X$ is

$$\mathcal{S}_{\text{time}}^{\lambda, x_0} : \mathcal{F}(T \rightarrow \mathbb{R}) \mapsto \mathcal{F}(T \times X \rightarrow \mathbb{R}), \quad f \mapsto [(t, x) \mapsto f(t - \frac{x-x_0}{\lambda})],$$

with the convention that $f(s) = 0$ if $s \notin T$. The *space shift operator* $\mathcal{S}_{\text{space}}^{\lambda, t_0}$ with speed $\lambda \in \mathbb{R}$ and initial time $t_0 \in T$ is

$$\mathcal{S}_{\text{space}}^{\lambda, t_0} : \mathcal{F}(X \rightarrow \mathbb{R}) \mapsto \mathcal{F}(T \times X \rightarrow \mathbb{R}), \quad g \mapsto [(t, x) \mapsto g(x - \lambda(t - t_0))],$$

with the convention that $f(y) = 0$ if $y \notin X$.

Consider the system (3.3a) with the initial condition (3.3b) and the boundary conditions (3.5). To ease the notation, let $K^- := \{1, \dots, n-r\}$ and $K^+ := \{n-r+1, \dots, n\}$. The solution to each scalar PDE (3.3a) can be found individually in terms of the initial condition $v_i^{t_0}(x)$, (3.3b) and boundary condition $v_i(t, b) =: v_i^b(t)$ in (3.5). The solution $\mathbf{v}(t, x)$ is expressed in terms of $\mathbf{v}_-(t, x)$ and $\mathbf{v}_+(t, x)$ separately below.

For left-going waves, the solution is of the form:

$$v_i(t, x) = \begin{cases} \left(\mathcal{S}_{\text{space}}^{\lambda_i, t_0} v_i^{t_0} \right) (t, x), & \text{if } x - b \leq \lambda_i(t - t_0), \\ \left(\mathcal{S}_{\text{time}}^{\lambda_i, b} v_i^b \right) (t, x), & \text{if } x - b > \lambda_i(t - t_0), \end{cases} \tag{3.6}$$

where $i \in K^-$ and $x \in [a, b]$. In a similar fashion, the solution to right-going waves is of the form:

$$v_j(t, x) = \begin{cases} \mathcal{S}_{\text{space}}^{\lambda_j, t_0} v_j^{t_0}, & \text{if } x - a \geq \lambda_j(t - t_0), \\ \mathcal{S}_{\text{time}}^{\lambda_j, a} v_j^a, & \text{if } x - a < \lambda_j(t - t_0), \end{cases} \tag{3.7}$$

where $j \in K^+$ and $x \in [a, b]$.

The solutions $\mathbf{v}_-(t, x)$ and $\mathbf{v}_+(t, x)$ together form the solution $\mathbf{v}(t, x)$ to the system (3.3a) with the initial condition (3.3b) and the boundary conditions (3.5). Hence, $\mathbf{v}(t, x)$ can be written as

$$\begin{aligned}
 \mathbf{v}(t, x) = & \sum_{i \in K^-} \begin{bmatrix} \text{diag}(\mathbf{e}_i) \\ \mathbf{0}_{r, n-r} \end{bmatrix} \left[\mathbb{1}_{\{x-b \leq \lambda_i(t-t_0)\}} \mathcal{S}_{\text{space}}^{\lambda_i, t_0} \mathbf{v}_-^{t_0} + \mathbb{1}_{\{x-b > \lambda_i(t-t_0)\}} \mathcal{S}_{\text{time}}^{\lambda_i, b} \mathbf{v}_-^b \right] (t, x) \\
 & + \sum_{j \in K^+} \begin{bmatrix} \mathbf{0}_{n-r, r} \\ \text{diag}(\mathbf{e}_{j-(n-r)}) \end{bmatrix} \left[\mathbb{1}_{\{x-a \geq \lambda_j(t-t_0)\}} \mathcal{S}_{\text{space}}^{\lambda_j, t_0} \mathbf{v}_+^{t_0} + \mathbb{1}_{\{x-a < \lambda_j(t-t_0)\}} \mathcal{S}_{\text{time}}^{\lambda_j, a} \mathbf{v}_+^a \right] (t, x),
 \end{aligned} \tag{3.8}$$

where $\mathbf{e}_i \in \mathbb{R}^{(n-r) \times (n-r)}$ and $\mathbf{e}_j \in \mathbb{R}^{r \times r}$ are the i -th and j -th directional unit vectors. The solutions at $x = a$ and $x = b$ then are of the form:

$$\begin{aligned}
 \mathbf{v}(t, a) &= \begin{bmatrix} \mathbf{0}_{n-r, r} \\ \mathbf{M}_2^{-1} \end{bmatrix} \mathbf{b}^a(t) + \begin{bmatrix} \mathbf{I}_{n-r, n-r} & \mathbf{0}_{n-r, r} \\ -\mathbf{M}_2^{-1} \mathbf{M}_1 & \mathbf{0}_{r, r} \end{bmatrix} \sum_{i \in K^-} \begin{bmatrix} \text{diag}(\mathbf{e}_i) \\ \mathbf{0}_{r, n-r} \end{bmatrix} \left(\mathcal{S}_{\text{time}}^{\lambda_i, b} \mathbf{v}_-^b \right) (t, a), \\
 \mathbf{v}(t, b) &= \begin{bmatrix} \mathbf{N}_1^{-1} \\ \mathbf{0}_{r, n-r} \end{bmatrix} \mathbf{b}^b(t) + \begin{bmatrix} \mathbf{0}_{n-r, n-r} & -\mathbf{N}_1^{-1} \mathbf{N}_2 \\ \mathbf{0}_{r, n-r} & \mathbf{I}_{r, r} \end{bmatrix} \sum_{j \in K^+} \begin{bmatrix} \mathbf{0}_{n-r, r} \\ \text{diag}(\mathbf{e}_{j-n+r}) \end{bmatrix} \left(\mathcal{S}_{\text{time}}^{\lambda_j, a} \mathbf{v}_+^a \right) (t, b).
 \end{aligned} \tag{3.9}$$

3.2 Solution framework for the linear hyperbolic system

In this section, the solution $\mathbf{u}(t, x)$ to the system (3.1) with the initial and boundary conditions (3.2) and (3.4) will be formulated by using the results from Sect. 3.1 and passing to the representation in the original variables, i.e. $\mathbf{u} = \mathbf{R}\mathbf{v}$.

Lemma 5 Consider the PDE (3.1) satisfying Assumption 1 and 2 with some given initial trajectory \mathbf{u}^0 as in (3.2) and boundary conditions $\mathbf{b}^a, \mathbf{b}^b$ as in (3.4). Let

$$\begin{aligned}
 \mathbf{u}^a(t) &:= \begin{cases} \sum_{i \in K^-} \mathfrak{F}_i \left(\mathcal{S}_{\text{space}}^{\lambda_i, t_0} \mathbf{u}^0 \right) (t, a), & t \leq t_0 + \frac{b-a}{\lambda_i} \\ \mathbf{F}_a \mathbf{b}^a(t) + \sum_{k=1}^n \mathbf{D}_k^{ab} \left(\mathcal{S}_{\text{time}}^{\lambda_k, b} \mathbf{u}^b \right) (t, a), & t > t_0 + \frac{b-a}{\lambda_k} \end{cases} \\
 \mathbf{u}^b(t) &:= \begin{cases} \sum_{j \in K^+} \mathfrak{F}_j \left(\mathcal{S}_{\text{space}}^{\lambda_j, t_0} \mathbf{u}^0 \right) (t, b), & t \leq t_0 + \frac{b-a}{-\lambda_j} \\ \mathbf{F}_b \mathbf{b}^b(t) + \sum_{k=1}^n \mathbf{D}_k^{ba} \left(\mathcal{S}_{\text{time}}^{\lambda_k, a} \mathbf{u}^a \right) (t, b), & t > t_0 + \frac{b-a}{\lambda_k} \end{cases}
 \end{aligned} \tag{3.10}$$

where $\mathfrak{F}_p := [\mathbf{R}^- \ \mathbf{R}^+] \text{diag}(\mathbf{e}_p) [\mathbf{R}^- \ \mathbf{R}^+]^{-1}$, with $\mathbf{e}_p \in \mathbb{R}^n$ is the p -th directional unit vector, $p = 1, 2, \dots, n$, $K^- = \{1, 2, \dots, n-r\}$, $K^+ = \{n-r+1, n-r+2, \dots, n\}$,

$$\mathbf{F}_a = \mathbf{R} \begin{bmatrix} \mathbf{0}_{n-r, r} \\ \mathbf{M}_2^{-1} \end{bmatrix} \quad \text{and} \quad \mathbf{F}_b = \mathbf{R} \begin{bmatrix} \mathbf{N}_1^{-1} \\ \mathbf{0}_{r, n-r} \end{bmatrix}, \tag{3.11a}$$

$$\mathbf{D}_p^{ab} = \mathbf{R} \begin{bmatrix} \mathbf{I}_{n-r, n-r} & \mathbf{0}_{n-r, r} \\ -\mathbf{M}_2^{-1} \mathbf{M}_1 & \mathbf{0}_{r, r} \end{bmatrix} \mathbf{R}^{-1} \mathfrak{F}_p \quad \text{and} \quad \mathbf{D}_p^{ba} = \mathbf{R} \begin{bmatrix} \mathbf{0}_{n-r, n-r} & -\mathbf{N}_1^{-1} \mathbf{N}_2 \\ \mathbf{0}_{r, n-r} & \mathbf{I}_{r, r} \end{bmatrix} \mathbf{R}^{-1} \mathfrak{F}_p, \tag{3.11b}$$

and where it is assumed that $\mathbf{u}^0(x) = 0$ for $x \notin [a, b]$. Then, every classical solution is given by

$$\mathbf{u}(t, x) = \sum_{i \in K^-} \mathfrak{S}_i \left(\mathcal{S}_{\text{time}}^{\lambda_i, b} \mathbf{u}^b \right) (t, x) + \sum_{j \in K^+} \mathfrak{S}_j \left(\mathcal{S}_{\text{time}}^{\lambda_j, a} \mathbf{u}^a \right) (t, x).$$

The proof is a direct consequence of the method of characteristics. Details can be found, for example, in [3].

Remark 6 In addition to the 2D shift operator defined as in Definition 4, we analogously define the 1D time shift operator $\mathcal{S}_{\text{time}}^\tau$ with $\tau \in \mathbb{R}$ for functions $f : T \subseteq \mathbb{R} \rightarrow \mathbb{R}$ as follows:

$$\mathcal{S}_{\text{time}}^\tau : \mathcal{F}(T \rightarrow \mathbb{R}) \mapsto \mathcal{F}(T \rightarrow \mathbb{R}), \quad f \mapsto [t \mapsto f(t - \tau)]. \tag{3.12}$$

where \mathcal{F} is as in Definition 4 and with the convention that $f(s) = 0$ if $s \notin T$.

Remark 7 Let $\mathbf{u}_{ab}(t) := (\mathbf{u}^a(t)^\top, \mathbf{u}^b(t)^\top)^\top \in \mathbb{R}^{2n}$, where $\mathbf{u}^a(t)$ and $\mathbf{u}^b(t)$ given as in (3.10). Below, we express \mathbf{u}_{ab} in a compressed form in terms of the 1D time shift operator $\mathcal{S}_{\text{time}}^\tau$

$$\mathbf{u}_{ab}(t) = \begin{bmatrix} \mathbf{F}_a & \mathbf{0}_{n, n-r} \\ \mathbf{0}_{n, r} & \mathbf{F}_b \end{bmatrix} \begin{bmatrix} \mathbf{b}^a(t) \\ \mathbf{b}^b(t) \end{bmatrix} + \sum_{k=1}^n \begin{bmatrix} \mathbf{0}_{n, n} & \mathbf{D}_k^{ab} \\ \mathbf{D}_k^{ba} & \mathbf{0}_{n, n} \end{bmatrix} (\mathcal{S}_{\text{time}}^{\tau_k} \mathbf{u}_{ab}(t)), \tag{3.13}$$

where $\tau_k = \frac{b-a}{\text{sgn}(\lambda_k)\lambda_k}$, the matrices $\mathbf{F}_a, \mathbf{F}_b, \mathbf{D}_k^{ab}, \mathbf{D}_k^{ba}, k = 1, 2, \dots, n$, are given as in (3.11) and the extensions of initial conditions as boundary conditions for the negative times are adapted as in the proof of Lemma 5. Then, the equality (3.13) follows from Eq. (3.10).

4 Switched differential-algebraic equations

In this section, we consider switched differential-algebraic equations (swDAEs) of the form:

$$\mathbf{E}_\sigma \dot{\mathbf{w}}(t) = \mathbf{H}_\sigma \mathbf{w}(t) + \mathbf{B}_\sigma \mathbf{q}(t) + \mathbf{f}_\sigma(t), \tag{4.1}$$

with the output $\mathbf{y}_D(t) := \mathbf{C}_{D\sigma} \mathbf{w}(t)$, where $\mathbf{w} : [t_0, \infty) \rightarrow \mathbb{R}^m, m \in \mathbb{N}$, is the state variable of the system, $\sigma : \mathbb{R} \rightarrow \{1, 2, \dots, N\}, N \in \mathbb{N}$, is a piecewise constant switching signal with a locally finite set of jump points and is right continuous, $\mathbf{E}_\xi, \mathbf{H}_\xi \in \mathbb{R}^{m \times m}$ for each $\xi \in \{1, 2, \dots, N\}$ and $\mathbf{f}_\xi : [t_0, \infty) \rightarrow \mathbb{R}^m$ is some inhomogeneity, $\mathbf{B}_\xi \in \mathbb{R}^{m \times \nu}, \mathbf{q} : [t_0, \infty) \rightarrow \mathbb{R}^\nu$ is the input, $\mathbf{y}_D \in \mathbb{R}^{m_1}, m_1 \in \mathbb{N}, \mathbf{C}_{D\xi} \in \mathbb{R}^{m_1 \times m}$. Note that the matrix \mathbf{E}_ξ is not assumed to be non-singular.

For the existence and uniqueness of solutions to (4.1), the following definition of regularity of matrix pairs will be employed.

Definition 8 (Regularity of a matrix pair) The matrix pencil $s\mathbf{E}_\xi - \mathbf{H}_\xi \in \mathbb{R}^{m \times n}[s], \xi \in \{1, 2, \dots, N\}, N \in \mathbb{N}$ is called *regular* if and only if $n = m$ and $\det(s\mathbf{E}_\xi - \mathbf{H}_\xi)$ is not the zero polynomial. The matrix pair $(\mathbf{E}_\xi, \mathbf{H}_\xi)$ and the corresponding mode ξ for the swDAE (4.1) are called *regular* if $s\mathbf{E}_\xi - \mathbf{H}_\xi$ is regular.

Due to the nonsingularity of E_g , solutions of (4.1) need to satisfy certain algebraic constraints which in general differ from each mode. Hence, at a switching time $t_s \in \mathbb{R}$ the value $\mathbf{w}(t_s^-)$ may be *inconsistent* with the mode after the switch, resulting in a jump in \mathbf{w} at t_s . In fact, derivatives of jumps, i.e. Dirac impulses, may also occur in response to switches [19]. Therefore, the solution space must be enlarged to distributions so that also jumps and Dirac impulses are allowed in the solutions. To this end, *piecewise-smooth distributions* are considered as the solution space. Below, we first recall the definition of scalar piecewise-smooth functions and distributions as in [17].

Definition 9 (Piecewise-smooth function/distribution) Let $T \subseteq \mathbb{R}$ be an open interval. A function $\alpha : T \rightarrow \mathbb{R}$ is called piecewise-smooth if and only if

$$\alpha = \sum_{i \in \mathbb{Z}} (\alpha_i)_{[t_i, t_{i+1})} \tag{4.2}$$

where the functions $\alpha_i : T \rightarrow \mathbb{R}$, $i \in \mathbb{Z}$, are (globally) smooth and the set $\{t_i \in T \mid i \in \mathbb{Z}\}$ is an ordered discrete set, i.e. $t_i < t_{i+1}$ for all $i \in \mathbb{Z}$ and the intersection with any compact subset of T only contains finitely many points. The set of all piecewise-smooth functions is denoted by $C_{pw}^\infty(T)$. A distribution $D \in \mathbb{D}(T)$ is called *piecewise-smooth* if

$$D = \alpha_{\mathbb{D}} + \sum_{\tau \in \Delta} D_\tau$$

where $\alpha \in C_{pw}^\infty$, $\Delta \subseteq T$ is a discrete set and $\text{supp } D_\tau \subseteq \{\tau\}$ for all $\tau \in \Delta$. The space of all piecewise-smooth distributions is denoted by $\mathbb{D}_{pw}C^\infty(T)$.

Note that a distribution D_τ has point support $\{\tau\}$ if and only if there exist $d_\tau \in \mathbb{N}$, $c_0, \dots, c_{d_\tau} \in \mathbb{R}$ such that

$$D_\tau = \sum_{i=0}^{d_\tau} c_i \delta_\tau^{(i)},$$

where $\delta_\tau^{(k)}$ is the k -th derivative of the Dirac impulse δ_τ at $\tau \in T$. It is easily seen that the space of piecewise-smooth distributions is closed with respect to differentiation and contains the space of piecewise-smooth functions as a subspace. In fact, a distribution is piecewise-smooth if, and only if, locally it is equal to a finite derivative of a piecewise-smooth function; in other words, for all $D \in \mathbb{D}_{pw}C^\infty$ and all compact subsets $K \subseteq T$ there exists $k \in \mathbb{N}$ and $\alpha \in C_{pw}^\infty(T; \mathbb{R})$ such that

$$D(\varphi) = (\alpha_{\mathbb{D}})^{(k)}(\varphi) \quad \forall \varphi \in C_0^\infty(T; \mathbb{R}) \text{ with } \text{supp } \varphi \subseteq K.$$

Having defined a suitable solution space $\mathbb{D}_{pw}C^\infty$ that allows distributions as solutions to the swDAE (4.1), the state variable \mathbf{w} , the input \mathbf{q} and the inhomogeneity \mathbf{f} in the swDAE (4.1) are considered in this solution space $\mathbb{D}_{pw}C^\infty$ and they are *vectors of distributions* in $\mathbb{D}_{pw}C^\infty$, i.e. $\mathbf{w}, \mathbf{f} \in (\mathbb{D}_{pw}C^\infty)^m$ and $\mathbf{q} \in (\mathbb{D}_{pw}C^\infty)^v$.

Theorem 10 (Existence and uniqueness of solutions of swDAEs, [17]) *Consider the swDAE as given in (4.1) with regular matrix pairs $(\mathbf{E}_\xi, \mathbf{H}_\xi)$ with $\xi \in \{1, 2, \dots, N\}$, and assume that the switching signal σ only has locally finitely many switches. Then, for every initial trajectory $\mathbf{w}^{t_0} \in (\mathbb{D}_{pw\mathcal{C}^\infty})^m$ with the initial time $t_0 \in \mathbb{R}$, any input $\mathbf{q} \in (\mathbb{D}_{pw\mathcal{C}^\infty})^v$ and any inhomogeneity $\mathbf{f}_\sigma \in (\mathbb{D}_{pw\mathcal{C}^\infty})^m$, there exists a unique globally defined solution $\mathbf{w} \in (\mathbb{D}_{pw\mathcal{C}^\infty})^m$ of the initial trajectory problem*

$$\begin{aligned} \mathbf{w}_{(-\infty, t_0)} &= \mathbf{w}_{(-\infty, t_0)}^{t_0}, \\ (\mathbf{E}_\sigma \dot{\mathbf{w}})_{[t_0, \infty)} &= (\mathbf{H}_\sigma \mathbf{w} + \mathbf{B}_\sigma \mathbf{q} + \mathbf{f}_\sigma)_{[t_0, \infty)}. \end{aligned} \tag{4.3}$$

Furthermore, the solution on $[t_0, \infty)$ is uniquely determined by $\mathbf{w}(t_0^-)$.

5 Distributional solution of the PDE

In Sect. 3, we have reviewed the classical solution to linear hyperbolic PDEs. But considering a coupling with switched DAEs, the boundary data for the PDE are given by piecewise-smooth distributions. Thus, we need to extend the solutions in the distributional sense, including Dirac impulses and its derivatives. Unfortunately, we cannot simply consider distributions on \mathbb{R}^2 , since we still need to evaluate the traces at initial time and the boundaries. Therefore, we construct an appropriate solution space by piecewise-smooth distributions in time and space.

5.1 Distribution theory in time and space

Definition 11 (Piecewise-smooth functions in time and space) Denote by $T \subseteq \mathbb{R}$ (time) and $X \subseteq \mathbb{R}$ (space) open intervals. We say a family of subsets $(P_i)_{i \in \mathcal{I}}$ of $T \times X$ for some index set \mathcal{I} is a *polyhedral partition* of $T \times X$ if and only if P_i are polyhedral sets (i.e. the intersection of finitely many open or closed half-spaces in $T \times X$), are pairwise disjoint and $\bigcup_{i \in \mathcal{I}} P_i = T \times X$.

A function $\beta : T \times X \rightarrow \mathbb{R}$ is called (*polyhedral*) *piecewise-smooth* if and only if there exists a locally finite polyhedral partition $\bigcup_{i \in \mathcal{I}} P_i$ of $T \times X$ and a family of smooth functions $\beta_i : T \times X \rightarrow \mathbb{R}$, $i \in \mathcal{I}$ such that

$$\beta = \sum_{i \in \mathcal{I}} \chi_{P_i} \beta_i, \tag{5.1}$$

where χ_{P_i} is the characteristic function of the set $P_i \subseteq T \times X$.

In the definition of a polyhedral partition $(P_i)_{i \in \mathcal{I}}$, it is not excluded that some P_i have empty interior (i.e. have measure zero), and this has the advantage that then the corresponding space of piecewise-smooth functions is closed under addition and restriction to polyhedral sets. For a piecewise-smooth function $\beta : T \times X \rightarrow \mathbb{R}$, it is easily seen that for any $t \in T$ and $x \in X$, the functions $\beta(t, \cdot)$ and $\beta(\cdot, x)$ are scalar

piecewise-smooth functions as in Definition 9 (where we treat two functions as equal when they are equal almost everywhere).

Definition 12 (Dirac segment, cf. [23]) Let $L \subseteq T \times X$ be a line segment, i.e. there exists $t_0, t_1 \in T, x_0, x_1 \in X$ such that

$$L = \{(t_0 + \xi(t_1 - t_0), x_0 + \xi(x_1 - x_0)) \mid \xi \in [0, 1]\}. \tag{5.2}$$

Then, the *Dirac segment* on L is

$$\delta_L : C_0^\infty(T \times X \rightarrow \mathbb{R}) \rightarrow \mathbb{R} : \varphi \mapsto \int_L \varphi,$$

where $\int_L \varphi$ is the usual line integral given by

$$\int_L \varphi = \int_0^1 \varphi(t_0 + \alpha(t_1 - t_0), x_0 + \alpha(x_1 - x_0)) \sqrt{\Delta t^2 + \Delta x^2} \, d\alpha,$$

where $\Delta t = t_1 - t_0$ and $\Delta x = x_1 - x_0$. For unbounded line segments (i.e. ξ ranges over an unbounded interval in (5.2)), the integral boundaries in the definition of $\int_L \varphi$ are replaced by $\pm\infty$ appropriately.

Note that if $\Delta t \neq 0$, then

$$\int_L \varphi = \int_{t_0}^{t_1} \varphi(t, x_0 + \frac{\Delta x}{\Delta t}(t - t_0)) \sqrt{1 + \frac{\Delta x^2}{\Delta t^2}} \, dt$$

and if $\Delta x \neq 0$ then

$$\int_L \varphi = \int_{x_0}^{x_1} \varphi(t_0 + \frac{\Delta t}{\Delta x}(x - x_0), x) \sqrt{1 + \frac{\Delta t^2}{\Delta x^2}} \, dx.$$

Lemma 13 Assume $T = \mathbb{R}, X = \mathbb{R}$ and consider the unbounded line $L = \{(t_0 + \lambda\Delta t, x_0 + \lambda\Delta x) \mid \lambda \in \mathbb{R}\}$ for some $t_0 \in T, x_0 \in X$ and $\Delta t > 0, \Delta x > 0$. For the step function along L given by

$$H_L(t, x) = \begin{cases} 1, & t - t_0 \geq \frac{\Delta t}{\Delta x}(x - x_0), \\ 0, & \text{otherwise} \end{cases} = \begin{cases} 1, & x - x_0 \leq \frac{\Delta x}{\Delta t}(t - t_0), \\ 0, & \text{otherwise} \end{cases}$$

we have

$$\partial_t H_{L\mathbb{D}} = \frac{1}{\sqrt{1 + (\frac{\Delta t}{\Delta x})^2}} \delta_L, \quad \partial_x H_{L\mathbb{D}} = -\frac{1}{\sqrt{1 + (\frac{\Delta x}{\Delta t})^2}} \delta_L$$

in particular,

$$\partial_t H_{L\mathbb{D}} = -\frac{\Delta x}{\Delta t} \partial_x H_{L\mathbb{D}}$$

Proof Recall the general definition of the partial derivative of a distribution D on $T \times X$:

$$(\partial_t D)(\varphi) := -D(\partial_t \varphi) \quad \text{and} \quad (\partial_x D)(\varphi) := -D(\partial_x \varphi).$$

Hence, we have

$$\begin{aligned} (\partial_t H_{L\mathbb{D}})(\varphi) &= - \int_X \int_T H_L(t, x) \partial_t \varphi(t, x) \, dt \, dx \\ &= - \int_{-\infty}^{\infty} \int_{t_0 + \frac{\Delta t}{\Delta x}(x-x_0)}^{\infty} \partial_t \varphi(t, x) \, dt \, dx \\ &= \int_{-\infty}^{\infty} \varphi(t_0 + \frac{\Delta t}{\Delta x}(x-x_0), x) \, dx = \frac{1}{\sqrt{1 + (\frac{\Delta t}{\Delta x})^2}} \int_L \varphi, \\ (\partial_x H_{L\mathbb{D}})(\varphi) &= - \int_T \int_X H_L(t, x) \partial_x \varphi(t, x) \, dx \, dt \\ &= - \int_{-\infty}^{\infty} \int_{-\infty}^{x_0 + \frac{\Delta x}{\Delta t}(t-t_0)} \partial_t \varphi(t, x) \, dx \, dt \\ &= - \int_{-\infty}^{\infty} \varphi(t, x_0 + \frac{\Delta x}{\Delta t}(t-t_0)) \, dt = - \frac{1}{\sqrt{1 + (\frac{\Delta x}{\Delta t})^2}} \int_L \varphi. \end{aligned}$$

From this, the claims follow. □

Corollary 14 *Let $P \subseteq T \times X$ be a polyhedral set with the line segments L_1, L_2, \dots, L_p as boundaries. Then, the partial derivative of $\chi_{P\mathbb{D}}$ is a linear combination of $\delta_{L_1}, \delta_{L_2}, \dots, \delta_{L_p}$.*

Definition 15 (Piecewise-smooth distributions in space and time) A distribution $D : C_0^\infty(T \times X) \rightarrow \mathbb{R}$ is called piecewise smooth if and only if there exists a piecewise-smooth function $\beta : T \times X \rightarrow \mathbb{R}$ and a locally finite family of line segments $(L_j)_{j \in \mathcal{J}}$ in $T \times X$ and coefficients $\alpha_j^{k,\ell} \in \mathbb{R}, k = 0, 1, \dots, n_j^t, \ell = 0, 1, \dots, n_j^x$ such that

$$D = \beta_{\mathbb{D}} + \sum_{j \in \mathcal{J}} \sum_{k,\ell} \alpha_j^{k,\ell} \partial_t^{(k)} \partial_x^{(\ell)} \delta_{L_j}. \tag{5.3}$$

The space of piecewise-smooth distributions on $T \times X$ is denoted by $\mathbb{D}_{pwC^\infty}(T \times X)$

Lemma 16 *Let $D \in \mathbb{D}_{pwC^\infty}(T \times X)$ given by (5.3) and (5.1), then*

1. $\partial_t D \in \mathbb{D}_{pwC^\infty}(T \times X)$ and $\partial_x D \in \mathbb{D}_{pwC^\infty}(T \times X)$;
2. *The restriction of D to any polyhedral set $P \subseteq T \times X$ given by $D_P := (\sum_{i \in \mathcal{I}} \chi_{P_i \cap P} \beta_i)_{\mathbb{D}} + \sum_{j \in \mathcal{J}} \sum_{k,\ell} \alpha_j^{k,\ell} (\partial_t)^k (\partial_x)^\ell \delta_{L_j \cap P}$ is well defined and is again a piecewise-smooth distribution.*

- Proof** 1. It suffices to show that the (partial) derivative of (the induced distribution by) a piecewise-smooth function (in the sense of Definition 11) is a piecewise-smooth distribution. Since the sum in (5.1) is locally finite, it furthermore suffices to consider only a single summand and since the multiplication with a smooth function is well defined for general distributions, it suffices to show that the partial derivatives of the indicator function χ_P for any polyhedral set $P \subseteq T \times X$ are a piecewise-smooth distribution, which was already established in Corollary 14.
2. First note that the intersection of two polyhedral sets is again a polyhedral set; hence, $\sum_{i \in \mathcal{I}} \chi_{P_i \cap P} \beta_i$ is a piecewise-smooth function. Furthermore, the intersection of a line-segment with a polyhedral set is again a line-segment (or empty); hence, D_P is again a piecewise-smooth distribution (taking into account the local finiteness property, which implies that evaluated at any test-function reduces to finite sums for which no convergence issues occur due to the restriction). \square

For any $(t, x) \in T \times X$, we want to define in the following the *partial evaluations* $D(t^+, \cdot)$, $D(t^-, \cdot)$, $D(\cdot, x^-)$, $D(\cdot, x^+)$ such that they are piecewise-smooth distributions on X or T , respectively, and such that (partial) differentiation commutes with the partial evaluation, i.e.

$$(\partial_x D)(t^\pm, \cdot) = D(t^\pm, \cdot)' \quad \text{and} \quad (\partial_t D)(\cdot, x^\pm) = D(\cdot, x^\pm)',$$

here $(\cdot)'$ denotes the (scalar) differentiation in $\mathbb{D}_{\text{pw}\mathcal{C}^\infty}(T)$ or $\mathbb{D}_{\text{pw}\mathcal{C}^\infty}(X)$, respectively. Clearly, for piecewise-smooth functions, such an evaluation is trivially defined. Due to commutativity requirement concerning differentiation and evaluation, it is also clear that it suffices to define the evaluation of Dirac segments. Due to Lemma 13, there is, however, only one possible choice:

$$\begin{aligned} \delta_L(t^+, \cdot) &:= \begin{cases} \sqrt{1 + \frac{\Delta x^2}{\Delta t^2}} \delta_{x_0 + \frac{\Delta x}{\Delta t}(t-t_0)}, & t \in [t_0, t_1), \\ 0, & \text{otherwise,} \end{cases} \\ \delta_L(t^-, \cdot) &:= \begin{cases} \sqrt{1 + \frac{\Delta x^2}{\Delta t^2}} \delta_{x_0 + \frac{\Delta x}{\Delta t}(t-t_0)}, & t \in (t_0, t_1], \\ 0, & \text{otherwise,} \end{cases} \\ \delta_L(\cdot, x^+) &:= \begin{cases} \sqrt{1 + \frac{\Delta t^2}{\Delta x^2}} \delta_{t_0 + \frac{\Delta t}{\Delta x}(x-x_0)}, & x \in [x_0, x_1), \\ 0, & \text{otherwise,} \end{cases} \\ \delta_L(\cdot, x^-) &:= \begin{cases} \sqrt{1 + \frac{\Delta t^2}{\Delta x^2}} \delta_{t_0 + \frac{\Delta t}{\Delta x}(x-x_0)}, & x \in (x_0, x_1], \\ 0, & \text{otherwise.} \end{cases} \end{aligned}$$

Definition 17 Let $D \in \mathbb{D}_{\text{pw}\mathcal{C}^\infty}(T \times X)$ given by (5.3) and (5.1). Then, for any $(t, x) \in T \times X$

$$D(t^\pm, \cdot) := \beta(t^\pm, \cdot)_{\mathbb{D}} + \sum_{j \in \mathcal{J}} \sum_{k, \ell} \alpha_j^{k, \ell} \partial_t^{(k)} \partial_x^{(\ell)} (\delta_{L_j}(t^\pm, \cdot)),$$

$$D(\cdot, x^\pm) := \beta(\cdot, x^\pm)_{\mathbb{D}} + \sum_{j \in \mathcal{J}} \sum_{k, \ell} \alpha_j^{k, \ell} \partial_t^{(k)} \partial_x^{(\ell)} (\delta_{L_j}(\cdot, x^\pm)).$$

5.2 Distributional solutions for linear hyperbolic PDE

Before addressing linear systems, we consider the scalar advection equation

$$\partial_t v + \lambda \partial_x v = 0, \tag{5.5}$$

where $\lambda \in \mathbb{R}$ is the wave speed and the initial condition is prescribed as

$$\mathbf{I.C.} \quad v(t_0^+, \cdot) = v^{t_0}, \tag{5.6}$$

where $v^{t_0} \in \mathbb{D}_{\text{pw}C^\infty}((a, b))$ and the boundary condition given as

$$\mathbf{B.C.} \quad \begin{cases} v(\cdot, a^+) = v^a, & \text{if } \lambda > 0, \\ v(\cdot, b^-) = v^b, & \text{if } \lambda < 0, \end{cases} \tag{5.7}$$

where $v^a, v^b \in \mathbb{D}_{\text{pw}C^\infty}((t_0, \infty))$.

We now expand the definition of the shift operator for continuous functions in Definition 4 to distributions.

Definition 18 (Shift operator for Dirac impulses) Let $T, X \subseteq \mathbb{R}$ be open intervals. The distributional time shift operator of a Dirac impulse at $t^* \in T$ $\delta_{t^*} \in \mathbb{D}_{\text{pw}C^\infty}(T)$ with speed λ and initial position x_0 is given by

$$S_{\text{time}}^{\lambda, x_0} \delta_{t^*} := \frac{1}{\sqrt{1 + \frac{1}{\lambda^2}}} \delta_{L_{\text{time}}^{\lambda, (t^*, x_0)}},$$

where $L_{\text{time}}^{\lambda, (t^*, x_0)} := \{(t, x) \mid t \in T, x = x_0 + \lambda(t - t^*) \in X\}$; the distributional space shift operator of a Dirac impulse $\delta_{x^*} \in \mathbb{D}_{\text{pw}C^\infty}(X)$ at $x^* \in X$ with speed λ and initial time t_0 is given by

$$S_{\text{space}}^{\lambda, t_0} \delta_{x^*} := \frac{1}{\sqrt{1 + \lambda^2}} \delta_{L_{\text{space}}^{\lambda, (t_0, x^*)}},$$

where $L_{\text{space}}^{\lambda, (t_0, x^*)} := \{(t, x) \mid x \in X, t = t_0 + (x - x^*)/\lambda \in T\}$.

Note that in the definition of the shift operator for Dirac impulses, the factors $1/\sqrt{1 + 1/\lambda^2}$ and $1/\sqrt{1 + \lambda^2}$ are necessary to obtain the following equalities:

$$\left(S_{\text{time}}^{\lambda, x_0} \delta_{t^*} \right) (\cdot, x^\pm) = \delta_{t^* + (x - x_0)/\lambda} \text{ and } \left(S_{\text{space}}^{\lambda, t_0} \delta_{x^*} \right) (t^\pm, \cdot) = \delta_{x^* + \lambda(t - t_0)}.$$

Fig. 5 PDE domain $(t_0, \infty) \times (a, b), \lambda > 0$. An example of Dirac impulses prescribed in initial and boundary conditions at certain locations in space, $x_m^*, m = \{1, 2, \dots, 7\}$, and time domains, $t_i^*, i = \{1, 2, 3, 4\}$, respectively. The green and pink lines correspond to the Dirac segments on these lines and show how Dirac impulses are shifted within the domain

In particular,

$$\left(S_{\text{time}}^{\lambda, x_0} \delta_{t^*} \right) (\cdot, x_0^\pm) = \delta_{t^*} \text{ and } \left(S_{\text{space}}^{\lambda, t_0} \delta_{x^*} \right) (t_0^\pm, \cdot) = \delta_{x^*}.$$

An illustration of the time- and space shift of Dirac impulses can also be found in Fig. 5.

Definition 19 (Shift operator for piecewise-smooth distributions) Let $D^T \in \mathbb{D}_{\text{pw}C^\infty}(T)$ and $D^X \in \mathbb{D}_{\text{pw}C^\infty}(X)$ be given by $D^T = d_{\mathbb{D}}^T + \sum_{t^* \in T^*} D_{t^*}^T$ and $D^X = d_{\mathbb{D}}^X + \sum_{x^* \in X^*} D_{x^*}^X$, where $d^T \in C_{\text{pw}}^\infty(T), d^X \in C_{\text{pw}}^\infty(X), T^* \subset T$ and $X^* \subset X$ are locally finite sets, and for each $t^* \in T^*$ and $x^* \in X^*$ we have $n^{t^*} \in \mathbb{N}$ and $n^{x^*} \in \mathbb{N}, c_i^{t^*} \in \mathbb{R}, i = 0, 1, \dots, n^{t^*}$ and $c_j^{x^*} \in \mathbb{R}, j = 0, 1, \dots, n^{x^*}$ such that

$$D_{t^*}^T = \sum_{i=0}^{n^{t^*}} c_i^{t^*} \partial_t^{(i)} \delta_{t^*} \text{ and } D_{x^*}^X = \sum_{j=0}^{n^{x^*}} c_j^{x^*} \partial_x^{(j)} \delta_{x^*}.$$

Then, the distributional time shift of D^T with speed λ and initial position x_0 is given by

$$S_{\text{time}}^{\lambda, x_0} D^T := (S_{\text{time}}^{\lambda, x_0} d^T)_{\mathbb{D}} + \sum_{t^* \in T^*} \sum_{i=0}^{n^{t^*}} c_i^{t^*} \partial_t^{(i)} S_{\text{time}}^{\lambda, x_0} \delta_{t^*},$$

and the distributional space shift of D^X with speed λ and initial time t_0 is given by

$$\mathcal{S}_{\text{space}}^{\lambda, t_0} D^X := (\mathcal{S}_{\text{space}}^{\lambda, t_0} d^X)_{\mathbb{D}} + \sum_{x^* \in X^*} \sum_{j=0}^{n^{x^*}} c_j^{x^*} \partial_x^{(j)} \mathcal{S}_{\text{space}}^{\lambda, t_0} \delta_{x^*}.$$

Assume $\lambda > 0$ and let v^{t_0} and v^a be given as in (5.6) and (5.7), respectively. Below, we will formulate the solution to the Eq. (5.5) in terms of the distributional space/time shift operators $\mathcal{S}_{\text{space}}^{\lambda, t_0}$, $\mathcal{S}_{\text{time}}^{\lambda, a}$. As seen in Sect. 3, since the solution is constant along the characteristics, exploiting the distributional space/time shift operator given in Definition 19, it can be written as

$$v(t^{\pm}, \cdot) = \left((\mathbb{1}_{\{x-a \geq \lambda(t-t_0)\}})_{\mathbb{D}} \mathcal{S}_{\text{space}}^{\lambda, t_0} v^{t_0} + (\mathbb{1}_{\{x-a < \lambda(t-t_0)\}})_{\mathbb{D}} \mathcal{S}_{\text{time}}^{\lambda, a} v^a \right) (t^{\pm}, \cdot), \tag{5.8a}$$

$$v(\cdot, x^{\pm}) = \left((\mathbb{1}_{\{x-a \geq \lambda(t-t_0)\}})_{\mathbb{D}} \mathcal{S}_{\text{space}}^{\lambda, t_0} v^{t_0} + (\mathbb{1}_{\{x-a < \lambda(t-t_0)\}})_{\mathbb{D}} \mathcal{S}_{\text{time}}^{\lambda, a} v^a \right) (\cdot, x^{\pm}). \tag{5.8b}$$

Then, the solution to the differential Eq. (5.5) at the right boundary with $\lambda > 0$ takes the form:

$$v(\cdot, b^-) = \left(\left(\mathbb{1}_{(t_0, t_0 + \frac{b-a}{\lambda})} \right)_{\mathbb{D}} \mathcal{S}_{\text{space}}^{\lambda, t_0} v^{t_0} + \left(\mathbb{1}_{(t_0 + \frac{b-a}{\lambda}, \infty)} \right)_{\mathbb{D}} \mathcal{S}_{\text{time}}^{\lambda, a} v^a \right) (\cdot, b^-),$$

which can be put in the form

$$v(\cdot, b^-) = \left(\mathcal{S}_{\text{time}}^{\lambda, a} v^a \right) (\cdot, b^-), \tag{5.9}$$

where $\left(\mathcal{S}_{\text{time}}^{\lambda, a} v^a \right) (\cdot, b^-) := \left(\mathcal{S}_{\text{space}}^{\lambda, t_0} v^{t_0} \right) (\cdot, b^-)$ on $(t_0, t_0 + \frac{b-a}{\lambda})$ with the convention that $v^{t_0} = 0$ outside (a, b) .

Now assume $\lambda < 0$ and let v^{t_0} and v^b be given as in (5.6) and (5.7), respectively, and let $v^{t_0} \in \mathbb{D}_{\text{pwC}^\infty}(X)$ and $v^b \in \mathbb{D}_{\text{pwC}^\infty}(T)$. The solution formulae to Eq. (5.5) with $\lambda < 0$ are now of the form:

$$v(t^{\pm}, \cdot) = \left((\mathbb{1}_{\{x-b \leq \lambda(t-t_0)\}})_{\mathbb{D}} \mathcal{S}_{\text{space}}^{\lambda, t_0} v^{t_0} + (\mathbb{1}_{\{x-b > \lambda(t-t_0)\}})_{\mathbb{D}} \mathcal{S}_{\text{time}}^{\lambda, b} v^b \right) (t^{\pm}, \cdot),$$

$$v(\cdot, x^{\pm}) = \left((\mathbb{1}_{\{x-b \leq \lambda(t-t_0)\}})_{\mathbb{D}} \mathcal{S}_{\text{space}}^{\lambda, t_0} v^{t_0} + (\mathbb{1}_{\{x-b > \lambda(t-t_0)\}})_{\mathbb{D}} \mathcal{S}_{\text{time}}^{\lambda, b} v^b \right) (\cdot, x^{\pm}).$$

Similarly, the solution to the differential Eq. (5.5) with $\lambda < 0$ at the left boundary can be written as:

$$v(\cdot, a^+) = \left(\left(\mathbb{1}_{(t_0, t_0 + \frac{b-a}{-\lambda})} \right)_{\mathbb{D}} \mathcal{S}_{\text{space}}^{\lambda, t_0} v^{t_0} + \left(\mathbb{1}_{(t_0 + \frac{b-a}{-\lambda}, \infty)} \right)_{\mathbb{D}} \mathcal{S}_{\text{time}}^{\lambda, b} v^b \right) (\cdot, a^+),$$

which is written as

$$v(\cdot, a^+) = \mathcal{S}_{\text{time}}^{\lambda, b} v^b(\cdot, a^+), \tag{5.10}$$

where $(\mathcal{S}_{\text{time}}^{\lambda, b} v^b)(\cdot, a^+) := (\mathcal{S}_{\text{space}}^{\lambda, t_0} v^{t_0})(\cdot, a^+)$ on $(t_0, t_0 + \frac{b-a}{-\lambda})$ with the convention that $v^{t_0} = 0$ outside (a, b) .

As a system of PDEs with boundary conditions, we consider

$$\partial_t \mathbf{u} + \mathbf{A} \partial_x \mathbf{u} = \mathbf{0}, \tag{5.11a}$$

I.C. $\mathbf{u}(t_0^+, \cdot) = \mathbf{u}^{t_0},$ (5.11b)

B.C. $\mathbf{P}_a \mathbf{u}(\cdot, a^+) = \mathbf{b}^a, \quad \text{and} \quad \mathbf{P}_b \mathbf{u}(\cdot, b^-) = \mathbf{b}^b,$ (5.11c)

with the unknown $\mathbf{u} \in (\mathbb{D}_{\text{pwC}^\infty}((t_0, \infty) \times (a, b)))^n$, the initial condition $\mathbf{u}^{t_0} \in (\mathbb{D}_{\text{pwC}^\infty}(a, b))^n$ and $\mathbf{b}^a \in (\mathbb{D}_{\text{pwC}^\infty}((t_0, \infty)))^r$, $\mathbf{b}^b \in (\mathbb{D}_{\text{pwC}^\infty}((t_0, \infty)))^{n-r}$ are left and right boundary conditions with $\mathbf{P}_a \in \mathbb{R}^{r \times n}$, and $\mathbf{P}_b \in \mathbb{R}^{(n-r) \times n}$.

As in Sect. 3 and with Assumption 1, the system is decomposed into its distributional characteristic variables $\mathbf{v} \in (\mathbb{D}_{\text{pwC}^\infty}((t_0, \infty) \times (a, b)))^n$ with the initial condition

$$\mathbf{v}(t_0^+, \cdot) = \begin{pmatrix} \mathbf{v}_-(t_0^+, \cdot) \\ \mathbf{v}_+(t_0^+, \cdot) \end{pmatrix} =: \begin{pmatrix} \mathbf{v}_-^{t_0} \\ \mathbf{v}_+^{t_0} \end{pmatrix}, \tag{5.12}$$

where $\mathbf{v}_-^{t_0} \in (\mathbb{D}_{\text{pwC}^\infty}(a, b))^{n-r}$, $\mathbf{v}_+^{t_0} \in (\mathbb{D}_{\text{pwC}^\infty}(a, b))^r$ and the boundary conditions take the form:

$$\mathbf{M} \mathbf{v}(\cdot, a^+) = \mathbf{b}^a, \quad \text{and} \quad \mathbf{N} \mathbf{v}(\cdot, b^-) = \mathbf{b}^b,$$

where the boundary conditions for the right- and left-going waves can be expressed as:

$$\mathbf{v}_+(\cdot, a^+) = \tilde{\mathbf{b}}_a, \tag{5.13a}$$

$$\mathbf{v}_-(\cdot, b^-) = \tilde{\mathbf{b}}_b, \tag{5.13b}$$

with $\tilde{\mathbf{b}}_a = (\mathbb{D}_{\text{pwC}^\infty}(T))^r$, $\tilde{\mathbf{b}}_b = (\mathbb{D}_{\text{pwC}^\infty}(T))^{n-r}$, $\mathbf{v} = (\mathbf{v}^-, \mathbf{v}^+)^T$ and $\mathbf{v}^{t_0} = (\mathbf{v}_-^{t_0}, \mathbf{v}_+^{t_0})^T$ where $\mathbf{v}_- \in (\mathbb{D}_{\text{pwC}^\infty}((t_0, \infty) \times (a, b)))^{n-r}$ stands for the left-going waves, whilst $\mathbf{v}_+ \in (\mathbb{D}_{\text{pwC}^\infty}((t_0, \infty) \times (a, b)))^r$ for the right-going waves.

The distributional solution \mathbf{v} to the decomposed system of (5.11a), as was done similarly to (3.3a), with the initial condition (5.12) and boundary conditions (5.13a)–(5.13b) can be written in terms of the solutions of the left- and right-going waves

$$\begin{aligned}
 \mathbf{v} = & \sum_{i \in K^-} \begin{bmatrix} \text{diag}(\mathbf{e}_i) \\ \mathbf{0}_{r,n-r} \end{bmatrix} \left((\mathbb{1}_{\{x-b \leq \lambda_i(t-t_0)\}})_{\mathbb{D}} \mathcal{S}_{\text{space}}^{\lambda_i, t_0} \mathbf{v}^{t_0} + (\mathbb{1}_{\{x-b > \lambda_i(t-t_0)\}})_{\mathbb{D}} \mathcal{S}_{\text{time}}^{\lambda_i, b} \tilde{\mathbf{b}}^b \right) \\
 & + \sum_{j \in K^+} \begin{bmatrix} \mathbf{0}_{n-r,r} \\ \text{diag}(\mathbf{e}_{j-(n-r)}) \end{bmatrix} \left((\mathbb{1}_{\{x-a \geq \lambda_j(t-t_0)\}})_{\mathbb{D}} \mathcal{S}_{\text{space}}^{\lambda_j, t_0} \mathbf{v}^{t_0} + (\mathbb{1}_{\{x-a < \lambda_j(t-t_0)\}})_{\mathbb{D}} \mathcal{S}_{\text{time}}^{\lambda_j, a} \tilde{\mathbf{b}}^a \right).
 \end{aligned} \tag{5.14}$$

The distributional solution \mathbf{u} to the IBVP system (5.11a)-(5.11b)-(5.11c) is now formulated via inversion of the distributional characteristic variables $\mathbf{u} = \mathbf{R}\mathbf{v}$. Let $\mathbf{5}_p := \mathbf{R} \text{diag}(\mathbf{e}_p) \mathbf{R}^{-1}$ with $\text{diag}(\mathbf{e}_p) \in \mathbb{R}^n$ is the p -th directional unit vector. The solution is

$$\begin{aligned}
 \mathbf{u} = & \sum_{i \in K^-} \mathbf{5}_i \left((\mathbb{1}_{\{x-b \leq \lambda_i(t-t_0)\}})_{\mathbb{D}} \mathcal{S}_{\text{space}}^{\lambda_i, t_0} \mathbf{u}^{t_0} + (\mathbb{1}_{\{x-b > \lambda_i(t-t_0)\}})_{\mathbb{D}} \mathcal{S}_{\text{time}}^{\lambda_i, b} \mathbf{u}^b \right) \\
 & + \sum_{j \in K^+} \mathbf{5}_j \left((\mathbb{1}_{\{x-a \geq \lambda_j(t-t_0)\}})_{\mathbb{D}} \mathcal{S}_{\text{space}}^{\lambda_j, t_0} \mathbf{u}^{t_0} + (\mathbb{1}_{\{x-a < \lambda_j(t-t_0)\}})_{\mathbb{D}} \mathcal{S}_{\text{time}}^{\lambda_j, a} \mathbf{u}^a \right),
 \end{aligned}$$

or, in the compact form

$$\mathbf{u} = \sum_{i \in K^-} \mathbf{5}_i \left(\mathcal{S}_{\text{time}}^{\lambda_i, b} \mathbf{u}^b \right) + \sum_{j \in K^+} \mathbf{5}_j \left(\mathcal{S}_{\text{time}}^{\lambda_j, a} \mathbf{u}^a \right), \tag{5.15}$$

where

$$\begin{cases} \left(\mathcal{S}_{\text{time}}^{\lambda_i, b} \mathbf{u}^b \right) := \sum_{i \in K^-} \mathbf{5}_i \left(\mathcal{S}_{\text{space}}^{\lambda_i, t_0} \mathbf{u}^{t_0} \right), & \text{on } (t_0, t_0 + \frac{b-x}{\lambda_i}), \\ \left(\mathcal{S}_{\text{time}}^{\lambda_j, a} \mathbf{u}^a \right) := \sum_{j \in K^+} \mathbf{5}_j \left(\mathcal{S}_{\text{space}}^{\lambda_j, t_0} \mathbf{u}^{t_0} \right), & \text{on } (t_0, t_0 + \frac{x-a}{\lambda_j}), \end{cases} \tag{5.16}$$

with the convention that $\mathbf{u}^{t_0} = 0$ outside (a, b) .

At the left and right end of the spatial domain, the distributional solution \mathbf{u} is as follows:

$$\begin{aligned}
 \mathbf{u}(\cdot, a^+) = & \mathbf{R} \begin{bmatrix} \mathbf{0}_{n-r,r} \\ \mathbf{M}_2^{-1} \end{bmatrix} \mathbf{b}^a(\cdot) + \mathbf{R} \begin{bmatrix} \mathbf{I}_{n-r,n-r} & \mathbf{0}_{n-r,r} \\ -\mathbf{M}_2^{-1} \mathbf{M}_1 & \mathbf{0}_{r,r} \end{bmatrix} \mathbf{R}^{-1} \sum_{i \in K^-} \mathbf{5}_i \left(\mathcal{S}_{\text{time}}^{\lambda_i, b} \mathbf{u}^b \right) (\cdot, a^+), \\
 \mathbf{u}(\cdot, b^-) = & \mathbf{R} \begin{bmatrix} \mathbf{N}_1^{-1} \\ \mathbf{0}_{r,n-r} \end{bmatrix} \mathbf{b}^b(\cdot) + \mathbf{R} \begin{bmatrix} \mathbf{0}_{n-r,n-r} & -\mathbf{N}_1^{-1} \mathbf{N}_2 \\ \mathbf{0}_{r,n-r} & \mathbf{I}_{r,r} \end{bmatrix} \mathbf{R}^{-1} \sum_{j \in K^+} \mathbf{5}_j \left(\mathcal{S}_{\text{time}}^{\lambda_j, a} \mathbf{u}^a \right) (\cdot, b^-),
 \end{aligned} \tag{5.17}$$

where $\mathbf{u}^a := \mathbf{u}(\cdot, a^+)$, $\mathbf{u}^b := \mathbf{u}(\cdot, b^-)$ and

$$\begin{cases} \left(\mathcal{S}_{\text{time}}^{\lambda_i, b} \mathbf{u}^b \right) (\cdot, a^+) := \sum_{i \in K^-} \mathbf{5}_i \left(\mathcal{S}_{\text{space}}^{\lambda_i, t_0} \mathbf{u}^{t_0} \right) (\cdot, a^+), & \text{on } (t_0, t_0 + \frac{b-a}{\lambda_i}), \\ \left(\mathcal{S}_{\text{time}}^{\lambda_j, a} \mathbf{u}^a \right) (\cdot, b^-) := \sum_{j \in K^+} \mathbf{5}_j \left(\mathcal{S}_{\text{space}}^{\lambda_j, t_0} \mathbf{u}^{t_0} \right) (\cdot, b^-), & \text{on } (t_0, t_0 + \frac{b-a}{\lambda_j}), \end{cases} \tag{5.18}$$

with the convention that $\mathbf{u}^{t_0} = 0$ outside (a, b) .

Remark 20 Similar to the 1D time shift defined in Remark 6, we define the 1D distributional time shift $\mathcal{S}_{\text{time}}^\tau$ for $D \in \mathbb{D}_{\text{pw}C^\infty}(T)$. Let $D \in \mathbb{D}_{\text{pw}C^\infty}(T)$ be given by $D = d_{\mathbb{D}} + \sum_{t^* \in T^*} D_{t^*}$, where $d \in C_{\text{pw}}^\infty(T)$, $T^* \subset T$ is a locally finite set, and for each $t^* \in T^*$ we have $n^{t^*} \in \mathbb{N}$, $c_i^{t^*} \in \mathbb{R}$, $i = 0, 1, \dots, n^{t^*}$ such that

$$D_{t^*} = \sum_{i=0}^{n^{t^*}} c_i^{t^*} \partial_t^{(i)} \delta_{t^*}.$$

Then, the 1D distributional time shift of D is given by

$$\mathcal{S}_{\text{time}}^\tau D := (\mathcal{S}_{\text{time}}^\tau d)_{\mathbb{D}} + \sum_{t^* \in T^*} \sum_{i=0}^{n^{t^*}} c_i^{t^*} \partial_t^{(i)} \mathcal{S}_{\text{time}}^\tau \delta_{t^*}.$$

Remark 21 Equation (5.17) can now be written in compressed form in terms of $\mathbf{u}_{ab} \in (\mathbb{D}_{\text{pw}C^\infty}(T))^{2n}$ and the 1D distributional time shift $\mathcal{S}_{\text{time}}^\tau$ as

$$\mathbf{u}_{ab} = \mathbf{F} \begin{bmatrix} \mathbf{b}^a \\ \mathbf{b}^b \end{bmatrix} + \sum_{k=1}^n \mathbf{D}_k \mathcal{S}_{\text{time}}^{\tau_k} \mathbf{u}_{ab}, \tag{5.19}$$

where $\tau_k = \frac{b-a}{\text{sgn}(\lambda_k)\lambda_k}$, $\mathbf{F} = \begin{bmatrix} \mathbf{F}_a & \mathbf{0}_{n,n-r} \\ \mathbf{0}_{n,r} & \mathbf{F}_b \end{bmatrix}$, $\mathbf{D}_k = \begin{bmatrix} \mathbf{0}_{n,n} & \mathbf{D}_k^{ab} \\ \mathbf{D}_k^{ba} & \mathbf{0}_{n,n} \end{bmatrix}$, $k = 1, 2, \dots, n$, where the matrices \mathbf{F}_a , \mathbf{F}_b , \mathbf{D}_k^{ab} , \mathbf{D}_k^{ba} are given as in (3.11). The extension of the initial conditions as the boundary conditions for the negative times is described in (5.18). Hence, the equality (5.19) follows from the equations in (5.17).

So far we have constructed a piecewise-smooth distributional solution to the hyperbolic PDE (5.11a). This solution is unique due to the following theorem.

Theorem 22 (Uniqueness of the distributional solution) *The solutions to (5.11a) are unique in the space of piecewise-smooth distributions.*

Proof As the PDE is linear, it is sufficient to show that $u \equiv 0$ is the only solution to the problem with zero initial and boundary conditions. First, we verify that δ_L can only be a solution to the i -th characteristic component of the PDE, if the segment has slope λ_i and crosses the boundary or initial time line

$$\begin{aligned} (\partial_t \delta_L)(\varphi) &= \int_{t_0}^{t_1} \partial_1 \varphi(t, x_0 + \frac{\Delta x}{\Delta t}(t - t_0)) \sqrt{1 + \frac{\Delta x^2}{\Delta t^2}} dt \\ (\partial_x \delta_L)(\varphi) &= \int_{t_0}^{t_1} \partial_2 \varphi(t, x_0 + \frac{\Delta x}{\Delta t}(t - t_0)) \sqrt{1 + \frac{\Delta x^2}{\Delta t^2}} dt \\ (\partial_t \delta_L + \lambda_i \partial_x \delta_L)(\varphi) &= \sqrt{1 + \frac{\Delta x^2}{\Delta t^2}} \int_{t_0}^{t_1} \frac{d}{dt} \varphi(t, x_0 + \frac{\Delta x}{\Delta t}(t - t_0)) \\ &\quad + (\lambda_i - \frac{\Delta x}{\Delta t}) \partial_2 \varphi(t, x_0 + \frac{\Delta x}{\Delta t}(t - t_0)) dt \end{aligned}$$

$$\begin{aligned}
 &= \sqrt{1 + \frac{\Delta x^2}{\Delta t^2}} \left(\varphi(t_1, x_1) - \varphi(t_0, x_0) \right) \\
 &\quad + \left(\lambda_i - \frac{\Delta x}{\Delta t} \right) \int_{t_0}^{t_1} \partial_2 \varphi(t, x_0 + \frac{\Delta x}{\Delta t} (t - t_0)) dt
 \end{aligned}$$

This expression is only zero for all φ , if $\lambda_i = \frac{\Delta x}{\Delta t}$ and (t_0, x_0) as well as (t_1, x_1) are outside of the support of the φ . Thus, the line has to have the slope according to the characteristic speed, and the line has to fully cross the considered domain. But at the points where the line hits the initial time or the boundaries of the domain, it has to satisfy the imposed conditions. Therefore, the strength of the impulse is equal to zero, i.e. the factor c for δ_L is zero. Due to linearity, the above computation can be extended directly to any combination of spatial and temporal derivatives of δ_L , which concludes the proof. \square

6 The coupled system

6.1 Existence and uniqueness of the coupled system

In this section, we consider the switched DAE (2.1d) with output \mathbf{y}_D given by (2.1e) together with the boundary behaviour $\mathbf{u}_{ab} := (\mathbf{u}(\cdot, a)^\top, \mathbf{u}(\cdot, b)^\top)^\top$ of the PDE (2.1a). Based on the results from the previous section, we can now relate the solution \mathbf{w} and \mathbf{u}_{ab} of the coupled system one-to-one with the solution of a switched delay DAE as follows.

Theorem 23 *Consider the coupled system (2.1) satisfying Assumptions 1 and 2. Then, $\mathbf{z} := (\mathbf{w}^\top, \mathbf{u}_{ab}^\top)^\top$ is a solution of the coupled system if and only if \mathbf{z} solves the switched delay DAE (swDDAE)*

$$\begin{bmatrix} \mathbf{E}_\sigma & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \dot{\mathbf{z}} = \begin{bmatrix} \mathbf{H}_\sigma & \mathbf{B}_\sigma \mathbf{C}_P \\ \mathbf{F} \mathbf{C}_{D\sigma} & -\mathbf{I} \end{bmatrix} \mathbf{z} + \sum_{k=1}^d \left(\begin{bmatrix} \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{D}_k \end{bmatrix} \mathcal{S}_{time}^{\tau_k} \mathbf{z} \right) + \begin{bmatrix} \mathbf{f}_\sigma \\ \mathbf{0} \end{bmatrix}, \quad (6.1)$$

where τ_k , \mathbf{u}_{ab} and the matrices \mathbf{F} and \mathbf{D}_k are given as in Remark 21 and its components as in (3.11).

Proof (\Leftarrow) Assume that $\mathbf{z} = (\mathbf{w}^\top, \mathbf{u}_{ab}^\top)^\top$ solves the swDDAE (6.1). From the swDDAE (6.1), we obtain

$$\mathbf{E}_\sigma \dot{\mathbf{w}} = \mathbf{H}_\sigma + \mathbf{B}_\sigma \mathbf{C}_P \mathbf{u}_{ab} + \mathbf{f}_\sigma,$$

for which \mathbf{w} is the solution with the input $\mathbf{q} = \mathbf{C}_P \mathbf{u}_{ab}$ as shown in Theorem 10. And also, from the swDDAE (6.1), we obtain

$$\mathbf{u}(\cdot, a^+) = \mathbf{F}_a \mathbf{b}^a + \sum_{i=1}^n \mathbf{D}_k^{ab} \left(\mathcal{S}_{time}^{\tau_k} \mathbf{u}^b \right)$$

$$\begin{aligned}
 &= \mathbf{F}_a \mathbf{b}^a + \sum_{i=1}^n \mathbf{D}_k^{ab} \left(\mathcal{S}_{\text{time}}^{\lambda_k, b} \mathbf{u}^b \right) (\cdot, a^+), \\
 \mathbf{u}^b(\cdot, b^-) &= \mathbf{F}_b \mathbf{b}^b + \sum_{i=1}^n \mathbf{D}_k^{ba} \left(\mathcal{S}_{\text{time}}^{\tau_k} \mathbf{u}^a \right) \\
 &= \mathbf{F}_b \mathbf{b}^b + \sum_{i=1}^n \mathbf{D}_k^{ba} \left(\mathcal{S}_{\text{time}}^{\lambda_k, a} \mathbf{u}^a \right) (\cdot, b^-),
 \end{aligned}$$

where $\begin{bmatrix} \mathbf{b}^a \\ \mathbf{b}^b \end{bmatrix} = \mathbf{C}_{D_\sigma} \mathbf{w}$, which together yield the solution \mathbf{u}

$$\mathbf{u} = \sum_{i \in K^-} \mathbf{5}_i \left(\mathcal{S}_{\text{time}}^{\lambda_i, b} \mathbf{u}^b \right) + \sum_{j \in K^+} \mathbf{5}_j \left(\mathcal{S}_{\text{time}}^{\lambda_j, a} \mathbf{u}^a \right),$$

where

$$\begin{cases} \left(\mathcal{S}_{\text{time}}^{\Lambda^-, b} \mathbf{u}^b \right) := \sum_{i \in K^-} \mathbf{5}_i \left(\mathcal{S}_{\text{space}}^{\lambda_i, t_0} \mathbf{u}^{t_0} \right), & \text{on } (t_0, t_0 + \frac{b-x}{-\lambda_i}), \\ \left(\mathcal{S}_{\text{time}}^{\Lambda^+, a} \mathbf{u}^a \right) := \sum_{j \in K^+} \mathbf{5}_j \left(\mathcal{S}_{\text{space}}^{\lambda_j, t_0} \mathbf{u}^{t_0} \right), & \text{on } (t_0, t_0 + \frac{x-a}{\lambda_j}), \end{cases} \tag{6.2}$$

with the convention that $\mathbf{u}^{t_0} = 0$ outside (a, b) and $\mathbf{5}_p := \mathbf{R} \text{diag}(\mathbf{e}_p) \mathbf{R}^{-1}$ with $\text{diag}(\mathbf{e}_p) \in \mathbb{R}^n$ is the p -th directional unit vector.

(\Rightarrow) Assume that \mathbf{w} is the solution to the swDDAE (2.1d)

$$\mathbf{E}_\sigma \dot{\mathbf{w}} = \mathbf{H}_\sigma \mathbf{w} + \mathbf{B}_\sigma \mathbf{y}_P + \mathbf{f}_\sigma,$$

where $\mathbf{y}_P = \mathbf{C}_P \mathbf{u}_{ab}$ and that \mathbf{u} is the solution to the PDE (2.1a) given as (5.15). Then \mathbf{u}_{ab} is of the form

$$\mathbf{u}_{ab}(t) = \mathbf{F} \mathbf{C}_{D_\sigma} \mathbf{w} + \sum_{k=1}^n \mathbf{D}_k \mathcal{S}_{\text{time}}^{\tau_k} \mathbf{u}_{ab},$$

where $\begin{bmatrix} \mathbf{b}^a \\ \mathbf{b}^b \end{bmatrix} = \mathbf{C}_{D_\sigma} \mathbf{w}$. Hence, $\mathbf{z} = (\mathbf{w}^\top, \mathbf{u}_{ab}^\top)^\top$ solves the swDDAE (6.1). □

Since the solution of the coupled system on the whole domain can be recovered via (5.15), we have therefore shown that the solution properties of the coupled system can be equivalently characterized by the swDDAE (6.1). The following result establishes conditions for existence and uniqueness of solutions for general swDDAE.

Theorem 24 (Existence and uniqueness of solutions for swDDAEs) *Consider the following switched delay differential-algebraic equations having $d \in \mathbb{N}$ delays such that $0 < \tau_1 < \tau_2 < \dots < \tau_d$*

$$\mathcal{E}_\sigma \dot{\mathbf{z}} = \mathcal{H}_\sigma \mathbf{z} + \sum_{j=1}^d \mathcal{D}_j \mathcal{S}_{\text{time}}^{\tau_j} \mathbf{z} + \mathbf{g}_\sigma, \tag{6.3}$$

with $\sigma : \mathbb{R} \rightarrow \{1, 2, \dots, N\}$, $N \in \mathbb{N}$, $\mathcal{E}_\xi, \mathcal{H}_\xi, \mathcal{D}_1, \dots, \mathcal{D}_d \in \mathbb{R}^{m \times m}$ for each $\xi \in \{1, 2, \dots, N\}$. Assume that $(\mathcal{E}_\xi, \mathcal{H}_\xi)$ is regular for each $\xi \in \{1, 2, \dots, N\}$, then for any initial trajectory $\mathbf{z}^{t_0} \in (\mathbb{D}_{pw}C^\infty)^m$ and any inhomogeneity $\mathbf{g}_\xi \in (\mathbb{D}_{pw}C^\infty)^m$, the corresponding initial trajectory problem has a unique solution.

Proof The result is a simple consequence from the “method of steps”, and the details for DDAEs with a single delay $d = 1$ can be found in [20]. In the following proof, we adapt the *prime* notation (\cdot') to indicate the derivative of distributions in addition to the *dot* notation ($\dot{\cdot}$) since the derivative of a distribution restricted to an interval and restricting a derivative of a distribution to an interval do not have the same meaning. In other words, the operations restriction to an interval and differentiation of a distribution do not commute.

Let τ be the smallest delay within the set $\{\tau_1, \dots, \tau_d\}$. The solution to the swDDAE system (6.3) is shown to be expressed as

$$\mathbf{z} = \mathbf{z}^{t_0}_{(-\infty, t_0)} + \sum_{k=1}^{\infty} \mathbf{z}^k_{[\tilde{t}_{k-1}, \tilde{t}_k]}, \tag{6.4}$$

where $\tilde{t}_k := t_0 + k\tau$, $k \in \mathbb{N}$, $\tilde{t}_0 := t_0$, and $\mathbf{z}^k \in (\mathbb{D}_{pw}C^\infty)^m$ is the unique solution to the non-delay swDAE, (Theorem 10),

$$\mathbf{z}^k_{(-\infty, \tilde{t}_{k-1})} = \mathbf{z}^{k-1}_{(-\infty, \tilde{t}_{k-1})} \tag{6.5a}$$

$$\left(\mathcal{E}_\sigma \dot{\mathbf{z}}^k\right)_{[\tilde{t}_{k-1}, \infty)} = \left(\mathcal{H}_\sigma \mathbf{z}^k + \tilde{\mathbf{g}}_\sigma\right)_{[\tilde{t}_{k-1}, \infty)} \tag{6.5b}$$

where $\tilde{\mathbf{g}}_\sigma := \left(\sum_{j=1}^d \mathcal{D}_j \mathcal{S}_{\text{time}}^{\tau_j} \mathbf{z}^{k-1} + \mathbf{g}_\sigma\right)$. For each $\varphi \in C_{pw}^\infty$, the formally infinite sum defining $\mathbf{z}(\varphi)$ is actually a finite sum, because φ has a compact support. Moreover, $\mathbf{z} \in (\mathbb{D}_{pw}C^\infty)^m$ since it is a linear combination of piecewise-smooth distributions. For any $k \geq 1$,

$$\begin{aligned} (\mathcal{E}_\sigma \dot{\mathbf{z}})_{[\tilde{t}_{k-1}, \tilde{t}_k)} &= \mathcal{E}_\sigma \left(\left(\mathbf{z}^{t_0}_{(-\infty, t_0)}\right)' + \sum_{p=1}^{\infty} \left(\mathbf{z}^p_{[\tilde{t}_{p-1}, \tilde{t}_p)}\right)' \right)_{[\tilde{t}_{k-1}, \tilde{t}_k)} \\ &= \mathcal{E}_\sigma \left(\dot{\mathbf{z}}^0_{(-\infty, t_0)} - \mathbf{z}^{t_0}(t_0^-) \delta_{t_0} \right. \\ &\quad \left. + \sum_{p=1}^{\infty} \left(\dot{\mathbf{z}}^p_{[\tilde{t}_{p-1}, \tilde{t}_p)} + \mathbf{z}^p(\tilde{t}_{p-1}^-) \delta_{\tilde{t}_{p-1}} - \mathbf{z}^p(\tilde{t}_p^-) \delta_{\tilde{t}_p} \right) \right)_{[\tilde{t}_{k-1}, \tilde{t}_k)} \\ &= \left(\mathcal{E}_\sigma \dot{\mathbf{z}}^k\right)_{[\tilde{t}_{k-1}, \tilde{t}_k)} \\ &= \left(\mathcal{H}_\sigma \mathbf{z}^k + \tilde{\mathbf{g}}_\sigma\right)_{[\tilde{t}_{k-1}, \tilde{t}_k)} \\ &= \mathcal{H}_\sigma \mathbf{z}_{[\tilde{t}_{k-1}, \tilde{t}_k)} + \mathcal{D} \left(\mathcal{S}_{\text{time}}^{\tau} \mathbf{z}^{k-1}\right)_{[\tilde{t}_{k-1}, \tilde{t}_k)} + \mathbf{g}_\sigma_{[\tilde{t}_{k-1}, \tilde{t}_k)} \end{aligned}$$

$$= (\mathcal{H}_\sigma \mathbf{z} + \mathcal{D}S_{\text{time}}^\tau \mathbf{z} + \mathbf{g}_\sigma)_{[\tilde{t}_{k-1}, \tilde{t}_k]},$$

where we exploit the relations from cf. [17], as $(D_{[s,t]})' = (D')_{[s,t]} + D(s^-)\delta_s - D(t^-)\delta_t$ and $(D_{(s,t)})' = (D')_{(s,t)} + D(s^+)\delta_s - D(t^-)\delta_t$, where $\delta_{\mp\infty} = 0$, with $-\infty \leq s \leq t \leq \infty$ and $D \in \mathbb{D}_{pwC^\infty}$. \square

Remark 25 The existence and uniqueness result of Theorem 24 can easily be extended to the case that the delay coefficient matrices $\mathcal{D}_j, j = 1, 2, \dots, d$ in (6.3) are switch dependent, i.e. (6.3) becomes

$$\mathcal{E}_\sigma \dot{\mathbf{z}} = \mathcal{H}_\sigma \mathbf{z} + \sum_{j=1}^d \mathcal{D}_{j,\sigma} S_{\text{time}}^{\tau_j} \mathbf{z} + \mathbf{g}_\sigma.$$

We can conclude now our main result about existence and uniqueness of solutions of the coupled system.

Corollary 26 Consider the coupled system (2.1) with a hyperbolic PDE (Assumption 1) and suitable boundary condition (Assumption 2). Furthermore, assume that for all $\xi \in \{1, \dots, N\}$ the matrix pairs $(\mathbf{E}_\xi, \mathbf{H}_\xi + \mathbf{B}_\xi \mathbf{C}_P \mathbf{F} \mathbf{C}_{D\xi})$ with \mathbf{F} as in Remark 21 are regular. Then, for any initial values $\mathbf{u}^{t_0} \in \mathbb{D}_{pwC^\infty}(X)^n, \mathbf{w}^{t_0} \in \mathbb{R}^m$ and external inhomogeneities $\mathbf{f}_\xi \in \mathbb{D}_{pwC^\infty}(T)^m$, there exists a unique solution $(\mathbf{u}, \mathbf{w}) \in \mathbb{D}_{pwC^\infty}(T \times X)^n \times \mathbb{D}_{pwC^\infty}(T)^m$ of the coupled system.

Proof This is a consequence of Theorems 23 and 24 and the fact that $\det(s\mathcal{E}_\xi - \mathcal{H}_\xi) = \det(s\mathbf{E}_\xi - (\mathbf{H}_\xi + \mathbf{B}_\xi \mathbf{C}_P \mathbf{F} \mathbf{C}_{D\xi}))$. \square

Remark 27 For general delay differential equations, it is common to distinguish the three types retarded, neutral and advanced, see, for example, [9,22]. For our existence and uniqueness result, we do not need any assumption on these different types and in general all three types are allowed. However, when numeric considerations are important, then it is necessary to further analyse the properties of the coupled systems with respect to the index and type of the resulting delay DAE; in particular, the question whether discontinuities in the initial data get smoothed out over time or not is highly relevant. This question was already investigated for nonswitched DDAEs [21] and it should be possible to extend these results to the switched case; this is ongoing research.

Remark 28 As illustrated already in Example 2, even if the PDE is well-defined and the swDAE is regular, coupling these systems may yield an ill-posed system. Indeed, using the notation of Corollary 26, we see that $\mathbf{F} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$ (note that \mathbf{F}_b is a 1×0 matrix) and hence

$$\begin{aligned} (\mathbf{E}, \mathbf{H} + \mathbf{B} \mathbf{C}_P \mathbf{F} \mathbf{C}_D) &= \left(\begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} + \begin{bmatrix} 0 \\ -1 \end{bmatrix} \cdot \begin{bmatrix} 1 & 0 \end{bmatrix} \cdot \begin{bmatrix} 1 \\ 0 \end{bmatrix} \cdot \begin{bmatrix} 0 & 1 \end{bmatrix} \right) \\ &= \left(\begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} \right) \end{aligned}$$

which is not a regular matrix pair anymore. Furthermore, the equivalent delay DAE according to Theorem 23 does not contain a delay term; hence, the closed-loop systems results in an DAE which is not regular.

6.2 Numerical results of the power grid example

In this section, we explain how we solve the coupled PDE system (2.5) with the switched DAE (2.10) numerically and illustrate the results obtained. We remark that the matrix pairs $(\mathcal{E}_\sigma, \mathcal{H}_\sigma)$ in the power grid example are regular.

Denote by $\mathcal{E} := \{1, 2, 3, 4\}$ the set of edges in the coupled network, over which we discretize the PDE. For discretizing the spatial domain $[a, b]$, we consider $x_k = a + k\Delta x, k = 0, 1, \dots, N, \Delta x = (b - a)/N$, where N is the number of cells in the mesh. We then insert two ghost cells G_{-1} and G_{N+1} at both ends of the computational domain which are treated as boundaries. The discretization of the time variable is done in accordance with the CFL number, which we choose to be 1, $t^{n+1} = t^n + \Delta t$. We denote by $\mathbf{u}_j^n = \mathbf{u}(x_j, t^n)$ the approximated solution at time t^n and position x_j . For the power grid example, denote by $(\mathbf{u}_k)_j^n = ((u_k^1)_j^n, (u_k^2)_j^n)^\top$ to have a suitable representation for the unknowns for every edge $k \in \mathcal{E}$. Before we start solving the coupled system at each time, we first decompose the discretized PDE over each edge $k \in \mathcal{E}$ into its characteristic variables $(\mathbf{v}_k)_j^n$ as left-going, $(v_k^-)_j^n$, and right-going characteristic waves, $(v_k^+)_j^n$, where $(u_k^1)_j^n = (v_k^-)_j^n + (v_k^+)_j^n$ and $(u_k^2)_j^n = -(v_k^-)_j^n + (v_k^+)_j^n$. To solve the decomposed PDE and the swDAE numerically, we use the upwind scheme and implicit Euler method, respectively. At each time iteration, we solve the decomposed PDE numerically, then we update $(\mathbf{u}_k)_j^{n+1}$ via inverse coordinate change $(\mathbf{u}_k)_j^{n+1} = \mathbf{R}_k(\mathbf{v}_k)_j^{n+1}$, where $(\mathbf{v}_k)_j^n = ((v_k^-)_j^n, (v_k^+)_j^n)^\top$ and $\mathbf{A}_k = \mathbf{R}_k \Lambda_k \mathbf{R}_k^{-1}$ for $k \in \mathcal{E}$, where \mathbf{A}_k is the coefficient matrix given as in (2.9). The equations in (2.7) together result in coupling conditions in terms of the characteristic variables as follows:

$$\begin{aligned} (v_2^-)_{N+1}^n &= 2(v_4^-)_{-1}^n - (v_2^+)_{N+1}^n, & (v_4^-)_{N+1}^n &= -\frac{2}{3}(v_3^-)_{N+1}^n + \frac{1}{3}(v_4^+)_{N+1}^n, \\ (v_4^+)_{-1}^n &= 2(v_2^+)_{N+1}^n - (v_4^-)_{-1}^n, & (v_3^-)_{N+1}^n &= \frac{1}{3}(v_3^+)_{N+1}^n - \frac{2}{3}(v_4^+)_{N+1}^n, \end{aligned}$$

which are four out of eight of boundary conditions for the decoupled PDE, and hence, they build up the inputs to the swDAE as

$$\begin{aligned} (u_4^1)_0^n &= (v_4^-)_{-1}^n + (v_4^+)_{-1}^n, & (u_2^1)_N^n &= (v_2^-)_{N+1}^n + (v_2^+)_{N+1}^n, \\ (u_3^1)_N^n &= (v_3^-)_{N+1}^n + (v_3^+)_{N+1}^n, & (u_4^1)_N^n &= (v_4^-)_{N+1}^n + (v_4^+)_{N+1}^n. \end{aligned}$$

The remaining four inputs to the swDAE are given in terms of characteristic variables $(v_1^-)_{-1}^n, (v_1^+)_{N+1}^n, (v_2^-)_{-1}^n$ and $(v_3^-)_{-1}^n$. Then, at each time step, we solve the swDAE and obtain the boundary conditions $(v_1^+)_{-1}^n, (v_1^-)_{N+1}^n, (v_2^+)_{-1}^n$ and $(v_3^+)_{-1}^n$. At P_1 in Fig. 4, the boundary condition is assigned as $(u_1^2)_0^n = v_G$, where v_G is prescribed constant voltage source, and hence, the boundary condition for the characteristics $(v_1^+)_{-1}^n = v_G + (v_1^-)_{-1}^n$. At P_2 over \mathcal{E}_1 , the input to the swDAE is $(u_1^1)_N^n = (v_1^-)_{N+1}^n + (v_1^+)_{N+1}^n$ and the boundary condition for the characteristic variable is $(u_1^2)_N^n = -(v_1^-)_{N+1}^n + (v_1^+)_{N+1}^n$. The swDAE assigns this boundary condition

Fig. 6 $t = 0.5$. After the first switch at $t = 0.4$, the peak on the 2nd edge occurs when the edge 1 and 2 are disconnected. On the 3rd and 4th edges, no changes have happened yet (hence, plots are not included here)

according to (2.8)

$$\left. \begin{aligned} i_{1\eta}^{n+1} &= (u_1^1)^n_N \\ v_{1\eta}^{n+1} &= \frac{d}{dt} i_{1\eta}^{n+1} \\ (u_1^2)^n_N &= v_{1\eta}^{n+1} \end{aligned} \right\} \Leftrightarrow \begin{cases} i_{1\eta}^{n+1} = 2(v_1^+)^n_N - v_{1\eta}^{n+1} \\ \frac{d}{dt} (2(v_1^+)^n_{N+1} - v_{1\eta}^{n+1}) = v_{1\eta}^{n+1} \\ (v_1^-)^n_{N+1} = (v_1^+)^n_N - v_{1\eta}^{n+1}, \end{cases}$$

where $\eta = 2$ or $\eta = 3$ depending on to which edge the switch connects \mathcal{E}_1 and $i_{12}^n, i_{13}^n, v_{12}^n, v_{13}^n$ are discretized state variables for the swDAE at time t^n . If $\eta = 2$, v_{12}^{n+1} is computed as above, then the boundary condition $(v_1^-)^n_{N+1} = (v_1^+)^n_N - v_{12}^{n+1}$ is assigned; hence, $i_{12}^{n+1} = (v_1^+)^n_N + (v_1^-)^n_{N+1}$. Furthermore, $i_{13}^{n+1} = 0$ and

$$\begin{aligned} v_{13}^{n+1} &= \frac{d}{dt} i_{13}^{n+1} \\ &= \frac{i_{13}^{n+1} - i_{13}^n}{\Delta t}. \end{aligned} \tag{6.8}$$

If $\eta = 3$, then $i_{12}^{n+1} = 0$ and v_{12}^{n+1} is found similarly as in (6.8). Then, the boundary conditions $(u_2^2)^n_0 = \kappa_{12} v_{12}^n$ and $(u_3^2)^n_0 = \kappa_{13} v_{13}^n$ are assigned; thus, the boundary conditions in characteristic variables $(v_2^+)^n_{-1} = (v_2^-)^n_{-1} + (u_2^2)^n_0$ and $(v_3^+)^n_{-1} = (v_3^-)^n_{-1} + (u_3^2)^n_0$ are assigned. Then, we update the solution for $(\mathbf{u}_k)_j^{n+1}$, for all $k \in \mathcal{E}$ by using the eigenvector matrix \mathbf{R}_k and $(v_k^-)^{n+1}_\ell$, $\ell = 0, 1, \dots, N$ and $(v_k^+)^{n+1}_\psi$, $\psi = 1, 2, \dots, N + 1$. Until we reach the prescribed final time, we update the time $t^{n+1} = t^n + \Delta t$ and repeat the above steps.

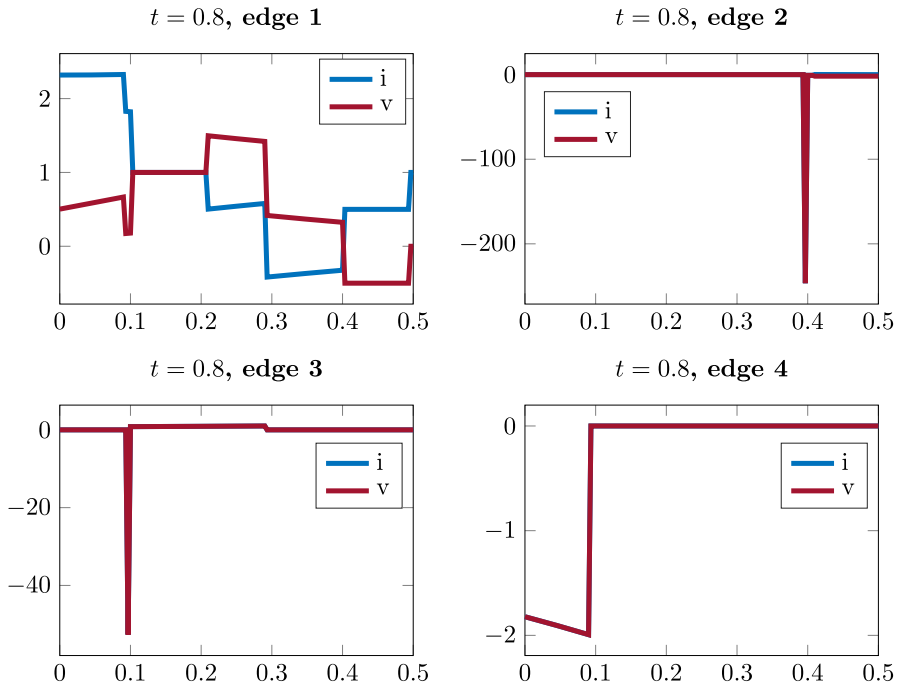

Fig. 7 $t = 0.8$. After the second switch at $t = 0.7$, switching transformer disconnects the edges 1 and 3, therefore, peak on the 3rd edge occurs. On the 4th edge, there has not been any changes yet

If, instead of solving for $(\mathbf{v}_k)_j^n$, one attempts to solve for $(\mathbf{u}_k)_j^n$ and assigns inputs/outputs without considering them in characteristic variables, oscillations might occur at boundaries at each time step. The method described in this section covers the Dirac impulses and ensures that such oscillations do not take place. Therefore, the numerical steps defined above should be carried out in characteristic variables, and then, the original unknown variables $(\mathbf{u}_k)_j^n$ should be updated accordingly.

6.2.1 Discontinuous initial condition

We consider the computational domain $[a, b] = [0, 0.5]$, initial time $t_0 = 0$, and final time $t_{max} = 1.5$, the number of cells $N = 150$, $\Delta x = 3.3 \times 10^{-3}$. The constant voltage at P_1 is $v_G = 0.5$. The constants are assumed to be $L_{12} = 1$, $L_{13} = 1$, $\kappa_{12} = 1$, $\kappa_{13} = 1$, $R_{24} = 1$, $R_{34} = 1$, $L_k = 1$ and $C_k = 1$ for each $k \in \mathcal{E}$. The initial conditions for the PDE are $I_1(0, x) = 0$, $x \in [0, 0.5]$, $V_1(0, x) = 0$ for $x \in [0, 0.3)$ and $V_1(0, x) = 1$ for $x \in [0.3, 0.5]$, $I_k(0, x) = 0$ and $V_k(0, x) = 0$, $x \in [0, 0.5]$, for $k = 2, 3, 4$. The switch initially connects the edges 1 and 2 for $t \in [0, 0.4)$ and then connects the edges 1 and 3 for $t \in [0.4, 0.7)$. For $t \in [0.7, 1.5)$, it connects the edges 1 and 2 again. In Fig. 6, the plots for \mathcal{E}_1 and \mathcal{E}_2 are shown at $t = 0.5$. After the first switch at $t = 0.4$, a Dirac impulse occurs on \mathcal{E}_2 .

In Fig. 7, the plots for all edges at $t = 0.8$ are shown. After the second switch at $t = 0.7$, there happens another Dirac impulse on \mathcal{E}_3 .

Fig. 8 PDE solutions on edges for the domain $(t, x) \in [0, 1.5] \times [0, 0.5]$. The switching times at $t = 0.4$ and $t = 0.7$. The plots on the left show values for I_k whereas on the right for V_k for the edges $k = 1, 2, 3, 4$, ($I_k = (u_k^2)$, $V_k = (u_k^1)$) in discretized variables)

And in Fig. 8, the solution over the whole domain $(t, x) \in [0, 1.5] \times [0, 0.5]$ is shown for all edges where the lines on \mathcal{E}_2 , \mathcal{E}_3 and \mathcal{E}_4 show how Dirac impulses move in the domain.

7 Conclusion

We have presented an existence and uniqueness result for solutions of linear hyperbolic PDE coupled to a linear switched DAE. Since switched DAEs can have distributional solutions (including Dirac impulses and their derivatives of arbitrary high order), it was necessary to first define a suitable distributional solution space for the PDE such that evaluation at the boundary (the trace operator) is well defined. Within this solution space (the space of piecewise-smooth distributions), it is possible to relate the solutions of the coupled systems with solutions of a delay switched DAE and we obtain our main result by extending recent results about the solvability of delay DAEs.

More research is still necessary to extend the results to PDEs with a source term as well as to the mildly nonlinear case. Furthermore, the well-posedness condition we present is still rather technical and there may be simpler sufficient condition, e.g. in terms of the coupling and output matrices of the PDE alone (which then rules out a situation as in Remark 28).
